| `object` | an object inheriting from class `"lme"`, representing a fitted linear mixed-effects model. |
| `...` | other optional fitted model objects inheriting from classes `"gls"`, `"gnls"`, `"lm"`, `"lme"`, `"lmList"`, `"nlme"`, `"nlsList"`, or `"nls"`. |

`test` an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by `object` and the objects in `...`. Defaults to `TRUE`.

`type` an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If `"sequential"`, the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if `"marginal"`, the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to `"sequential"`.

`adjustSigma` an optional logical value. If `TRUE` and the estimation method used to obtain `object` was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$, converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is `TRUE`.

`Terms` an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is `NULL`.

`L` an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is `NULL`.

`x` an object inheriting from class `"anova.lme"`

`verbose` an optional logical value. If `TRUE`, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if `verbose = FALSE`. Defaults to `FALSE`.

## Value

a data frame inheriting from class `"anova.lme"`.

## Note

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

---

`as.matrix.corStruct` *Matrix of a corStruct Object*

---

## Description

This method function extracts the correlation matrix, or list of correlation matrices, associated with `object`.

### Usage

```
## S3 method for class 'corStruct'
as.matrix(x, ...)
```

### Arguments

| | |
|---|---|
| x | an object inheriting from class "corStruct", representing a correlation structure. |
| ... | further arguments passed from other methods. |

### Value

If the correlation structure includes a grouping factor, the returned value will be a list with components given by the correlation matrices for each group. Otherwise, the returned value will be a matrix representing the correlation structure associated with object.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

### See Also

## as.matrix.pdMat *Matrix of a pdMat Object*

---

### Description

This method function extracts the positive-definite matrix represented by x.

### Usage

```
## S3 method for class 'pdMat'
as.matrix(x, ...)
```

### Arguments

| | |
|---|---|
| x | an object inheriting from class "pdMat", representing a positive-definite matrix. |
| ... | further arguments passed from other methods. |

### Value

a matrix corresponding to the positive-definite matrix represented by `x`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

as.matrix(pdSymm(diag(4)))
```

---

## `as.matrix.reStruct` *Matrices of an reStruct Object*

---

### Description

This method function extracts the positive-definite matrices corresponding to the `pdMat` elements of `object`.

### Usage

```
## S3 method for class 'reStruct'
as.matrix(x, ...)
```

### Arguments

| | |
|---|---|
| `x` | an object inheriting from class "`reStruct`", representing a random effects structure and consisting of a list of `pdMat` objects. |
| `...` | further arguments passed from other methods. |

### Value

a list with components given by the positive-definite matrices corresponding to the elements of `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

## asOneFormula *Combine Formulas of a Set of Objects*

---

### Description

The names of all variables used in the formulas extracted from the objects defined in ... are converted into a single linear formula, with the variables names separated by +.

### Usage

```
asOneFormula(..., omit)
```

### Arguments

| | |
|---|---|
| ... | objects, or lists of objects, from which a formula can be extracted. |
| omit | an optional character vector with the names of variables to be omitted from the returned formula. Defaults to c(".", "pi"). |

### Value

a one-sided linear formula with all variables named in the formulas extracted from the objects in ..., except the ones listed in omit.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

formula, all.vars

### Examples

```
asOneFormula(y ~ x + z | g, list(~ w, ~ t * sin(2 * pi)))
```

## Assay — *Bioassay on Cell Culture Plate*

### Description

The `Assay` data frame has 60 rows and 4 columns.

### Format

This data frame contains the following columns:

**Block** an ordered factor with levels `2 < 1` identifying the block where the wells are measured.

**sample** a factor with levels `a` to `f` identifying the sample corresponding to the well.

**dilut** a factor with levels `1` to `5` indicating the dilution applied to the well

**logDens** a numeric vector of the log-optical density

### Details

These data, courtesy of Rich Wolfe and David Lansky from Searle, Inc., come from a bioassay run on a 96-well cell culture plate. The assay is performed using a split-block design. The 8 rows on the plate are labeled A–H from top to bottom and the 12 columns on the plate are labeled 1–12 from left to right. Only the central 60 wells of the plate are used for the bioassay (the intersection of rows B–G and columns 2–11). There are two blocks in the design: Block 1 contains columns 2–6 and Block 2 contains columns 7–11. Within each block, six samples are assigned randomly to rows and five (serial) dilutions are assigned randomly to columns. The response variable is the logarithm of the optical density. The cells are treated with a compound that they metabolize to produce the stain. Only live cells can make the stain, so the optical density is a measure of the number of cells that are alive and healthy.

## asTable — *Convert groupedData to a matrix*

### Description

Create a tabular representation of the response in a balanced groupedData object.

### Usage

```
asTable(object)
```

### Arguments

| | |
|---|---|
| `object` | A balanced `groupedData` object |

## Details

A balanced groupedData object can be represented as a matrix or table of response values corresponding to the values of a primary covariate for each level of a grouping factor. This function creates such a matrix representation of the data in `object`.

## Value

A matrix. The data in the matrix are the values of the response. The columns correspond to the distinct values of the primary covariate and are labelled as such. The rows correspond to the distinct levels of the grouping factor and are labelled as such.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

## See Also

`groupedData`, `isBalanced`, `balancedGrouped`

## Examples

```
asTable(Orthodont)

# Pinheiro and Bates, p. 109
ergoStool.mat <- asTable(ergoStool)
```

---

`augPred` *Augmented Predictions*

---

## Description

Predicted values are obtained at the specified values of `primary`. If `object` has a grouping structure (i.e. `getGroups(object)` is not `NULL`), predicted values are obtained for each group. If `level` has more than one element, predictions are obtained for each level of the `max(level)` grouping factor. If other covariates besides `primary` are used in the prediction model, their average (numeric covariates) or most frequent value (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

## Usage

```
augPred(object, primary, minimum, maximum, length.out, ...)

## S3 method for class 'lme'
augPred(object, primary = NULL,
        minimum = min(primary), maximum = max(primary),
        length.out = 51, level = Q, ...)
```

## Arguments

| | |
|---|---|
| `object` | a fitted model object from which predictions can be extracted, using a `predict` method. |
| `primary` | an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate `object` (using `getCovariate`), it will be used as `primary`. |
| `minimum` | an optional lower limit for the primary covariate. Defaults to `min(primary)`. |
| `maximum` | an optional upper limit for the primary covariate. Defaults to `max(primary)`. |
| `length.out` | an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51. |
| `level` | an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level. |
| `...` | some methods for the generic may require additional arguments. |

## Value

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if `object` does not have a grouping structure, all elements will be `1`), the predicted or observed values, and the type of value in the third column: `original` for the observed values and `predicted` (single or no grouping factor) or `predict.groupVar` (multiple levels of grouping), with `groupVar` replaced by the actual grouping variable name (`fixed` is used for population predictions). The returned object inherits from class `"augPred"`.

## Note

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

## See Also

`plot.augPred`, `getGroups`, `predict`

## Examples

```
fm1 <- lme(Orthodont, random = ~1)
augPred(fm1, length.out = 2, level = c(0,1))
```

balancedGrouped *Create a groupedData object from a matrix*

## Description

Create a groupedData object from a data matrix. This function can be used only with balanced data. The opposite conversion, from a groupedData object to a matrix, is done with asTable.

## Usage

```
balancedGrouped(form, data, labels=NULL, units=NULL)
```

## Arguments

| | |
|---|---|
| form | A formula of the form y ~ x \| g giving the name of the response, the primary covariate, and the grouping factor. |
| data | A matrix or data frame containing the values of the response grouped according to the levels of the grouping factor (rows) and the distinct levels of the primary covariate (columns). The dimnames of the matrix are used to construct the levels of the grouping factor and the primary covariate. |
| labels | an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named x and that for the response is named y. Either label can be omitted. |
| units | an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named x and that for the response is named y. Either units string can be omitted. |

## Value

A balanced groupedData object.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

## See Also

groupedData, isBalanced, asTable

## Examples

```
OrthoMat <- asTable( Orthodont )
Orth2 <- balancedGrouped(distance ~ age | Subject, data = OrthoMat,
    labels = list(x = "Age",
                  y = "Distance from pituitary to pterygomaxillary fissure"),
    units = list(x = "(yr)", y = "(mm)"))
Orth2[ 1:10, ]        ## check the first few entries
```

```
# Pinheiro and Bates, p. 109
ergoStool.mat <- asTable(ergoStool)
balancedGrouped(effort~Type|Subject,
                data=ergoStool.mat)
```

---

bdf *Language scores*

---

## Description

The bdf data frame has 2287 rows and 25 columns of language scores from grade 8 pupils in elementary schools in The Netherlands.

## Usage

```
data(bdf)
```

## Format

**schoolNR** a factor denoting the school.

**pupilNR** a factor denoting the pupil.

**IQ.verb** a numeric vector of verbal IQ scores

**IQ.perf** a numeric vector of IQ scores.

**sex** Sex of the student.

**Minority** a factor indicating if the student is a member of a minority group.

**repeatgr** an ordered factor indicating if one or more grades have been repeated.

**aritPRET** a numeric vector

**classNR** a numeric vector

**aritPOST** a numeric vector

**langPRET** a numeric vector

**langPOST** a numeric vector

**ses** a numeric vector of socioeconomic status indicators.

**denomina** a factor indicating of the school is a public school, a Protestant private school, a Catholic private school, or a non-denominational private school.

**schoolSES** a numeric vector

**satiprin** a numeric vector

**natitest** a factor with levels 0 and 1

**meetings** a numeric vector

**currmeet** a numeric vector

**mixedgra** a factor indicating if the class is a mixed-grade class.

**percmino** a numeric vector

**aritdiff** a numeric vector

**homework** a numeric vector

**classsiz** a numeric vector

**groupsiz** a numeric vector

BodyWeight *Rat weight over time for different diets*

---

## Description

The BodyWeight data frame has 176 rows and 4 columns.

## Format

This data frame contains the following columns:

**weight** a numeric vector giving the body weight of the rat (grams).

**Time** a numeric vector giving the time at which the measurement is made (days).

**Rat** an ordered factor with levels 2 < 3 < 4 < 1 < 8 < 5 < 6 < 7 < 11 < 9 < 10 < 12 < 13 < 15 < 14 < 16 identifying the rat whose weight is measured.

**Diet** a factor with levels 1 to 3 indicating the diet that the rat receives.

## Details

Hand and Crowder (1996) describe data on the body weights of rats measured over 64 days. These data also appear in Table 2.4 of Crowder and Hand (1990). The body weights of the rats (in grams) are measured on day 1 and every seven days thereafter until day 64, with an extra measurement on day 44. The experiment started several weeks before "day 1." There are three groups of rats, each on a different diet.

## Cefamandole — *Pharmacokinetics of Cefamandole*

### Description

The `Cefamandole` data frame has 84 rows and 3 columns.

### Format

This data frame contains the following columns:

**Subject** a factor giving the subject from which the sample was drawn.

**Time** a numeric vector giving the time at which the sample was drawn (minutes post-injection).

**conc** a numeric vector giving the observed plasma concentration of cefamandole (mcg/ml).

### Details

Davidian and Giltinan (1995, 1.1, p. 2) describe data obtained during a pilot study to investigate the pharmacokinetics of the drug cefamandole. Plasma concentrations of the drug were measured on six healthy volunteers at 14 time points following an intraveneous dose of 15 mg/kg body weight of cefamandole.

Davidian, M. and Giltinan, D. M. (1995), *Nonlinear Models for Repeated Measurement Data*, Chapman and Hall, London.

### Examples

```
plot(Cefamandole)
fm1 <- nlsList(SSbiexp, data = Cefamandole)
summary(fm1)
```

## Coef — *Assign Values to Coefficients*

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "`pdMat`", "`corStruct`" and "`varFunc`" classes, "`reStruct`", and "`modelStruct`".

### Usage

```
coef(object, ...) <-  value
```

### Arguments

| | |
|---|---|
| object | any object representing a fitted model, or, by default, any object with a coef component. |
| ... | some methods for this generic function may require additional arguments. |
| value | a value to be assigned to the coefficients associated with object. |

### Value

will depend on the method function; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

coef

### Examples

```
## see the method function documentation
```

---

## coef.corStruct *Coefficients of a corStruct Object*

---

### Description

This method function extracts the coefficients associated with the correlation structure represented by object.

### Usage

```
## S3 method for class 'corStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'corStruct'
coef(object, ...) <- value
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "corStruct", representing a correlation structure. |
| unconstrained | a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE. |
| value | a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of coef{object} and must be given in unconstrained form. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

a vector with the coefficients corresponding to `object`.

### SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`. `Object` must be initialized (using `Initialize`) before new values can be assigned to its coefficients.

### Author(s)

José Pinheiro and Douglas Bates

### References

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

### Examples

```
cst1 <- corARMA(p = 1, q = 1)
coef(cst1)
```

---

## `coef.gnls` *Extract gnls Coefficients*

---

### Description

The estimated coefficients for the nonlinear model represented by `object` are extracted.

### Usage

```
## S3 method for class 'gnls'
coef(object, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`gnls`", representing a generalized nonlinear least squares fitted model. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

a vector with the estimated coefficients for the nonlinear model represented by `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

gnls

## Examples

```
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
            weights = varPower())
coef(fm1)
```

---

coef.lme *Extract lme Coefficients*

---

## Description

The estimated coefficients at level $i$ are obtained by adding together the fixed effects estimates and the corresponding random effects estimates at grouping levels less or equal to $i$. The resulting estimates are returned as a data frame, with rows corresponding to groups and columns to coefficients. Optionally, the returned data frame may be augmented with covariates summarized over groups.

## Usage

```
## S3 method for class 'lme'
coef(object, augFrame, level, data, which, FUN,
       omitGroupingFactor, subset, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "lme", representing a fitted linear mixed-effects model. |
| augFrame | an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE. |
| level | an optional positive integer giving the level of grouping to be used in extracting the coefficients from an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping. |
| data | an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object. |
| which | an optional positive integer or character vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data. |
| FUN | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean |

for numeric factors, and `Mode` for both `factor` and `ordered`. The `Mode` function, defined internally in `gsummary`, returns the modal or most popular value of the variable. It is different from the `mode` function that returns the S-language mode of the variable.

`omitGroupingFactor`
: an optional logical value. When `TRUE` the grouping factor itself will be omitted from the group-wise summary of `data` but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to `FALSE`.

`subset`
: an optional expression specifying a subset

`...`
: some methods for this generic require additional arguments. None are used in this method.

## Value

a data frame inheriting from class `"coef.lme"` with the estimated coefficients at level `level` and, optionally, other covariates summarized over groups. The returned object also inherits from classes `"ranef.lme"` and `"data.frame"`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York, esp. pp. 455-457.

## See Also

`lme`, `ranef.lme`, `plot.ranef.lme`, `gsummary`

## Examples

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
coef(fm1)
coef(fm1, augFrame = TRUE)
```

---

`coef.lmList` *Extract lmList Coefficients*

---

## Description

The coefficients of each `lm` object in the `object` list are extracted and organized into a data frame, with rows corresponding to the `lm` components and columns corresponding to the coefficients. Optionally, the returned data frame may be augmented with covariates summarized over the groups associated with the `lm` components.

## Usage

```
## S3 method for class 'lmList'
coef(object, augFrame, data, which, FUN,
   omitGroupingFactor, ...)
```

### Arguments

- `object` — an object inheriting from class "lmList", representing a list of lm objects with a common model.
- `augFrame` — an optional logical value. If TRUE, the returned data frame is augmented with variables defined in the data frame used to produce object; else, if FALSE, only the coefficients are returned. Defaults to FALSE.
- `data` — an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.
- `which` — an optional positive integer or character vector specifying which columns of the data frame used to produce object should be used in the augmentation of the returned data frame. Defaults to all variables in the data.
- `FUN` — an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing the data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.
- `omitGroupingFactor` — an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.
- `...` — some methods for this generic require additional arguments. None are used in this method.

### Value

a data frame inheriting from class "coef.lmList" with the estimated coefficients for each "lm" component of object and, optionally, other covariates summarized over the groups corresponding to the "lm" components. The returned object also inherits from classes "ranef.lmList" and "data.frame".

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York, esp. pp. 457-458.

### See Also

lmList, fixed.effects.lmList, ranef.lmList, plot.ranef.lmList, gsummary

## Examples

```
fm1 <- lmList(distance ~ age|Subject, data = Orthodont)
coef(fm1)
coef(fm1, augFrame = TRUE)
```

---

`coef.modelStruct` *Extract modelStruct Object Coefficients*

---

## Description

This method function extracts the coefficients associated with each component of the `modelStruct` list.

## Usage

```
## S3 method for class 'modelStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'modelStruct'
coef(object, ...) <- value
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`modelStruct`", representing a list of model components, such as "`corStruct`" and "`varFunc`" objects. |
| `unconstrained` | a logical value. If `TRUE` the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If `FALSE` the coefficients are returned in "natural", possibly constrained, form. Defaults to `TRUE`. |
| `value` | a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef{object}` and must be given in unconstrained form. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

a vector with all coefficients corresponding to the components of `object`.

## SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`. `Object` must be initialized (using `Initialize`) before new values can be assigned to its coefficients.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

`Initialize`

## Examples

```
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
   corStruct = corAR1(0.3))
coef(lms1)
```

---

`coef.pdMat` *pdMat Object Coefficients*

---

## Description

This method function extracts the coefficients associated with the positive-definite matrix represented by `object`.

## Usage

```
## S3 method for class 'pdMat'
coef(object, unconstrained, ...)
## S3 replacement method for class 'pdMat'
coef(object, ...) <- value
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`pdMat`", representing a positive-definite matrix. |
| `unconstrained` | a logical value. If `TRUE` the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If `FALSE` the upper triangular elements of the positive-definite matrix represented by `object` are returned. Defaults to `TRUE`. |
| `value` | a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef{object}` and must be given in unconstrained form. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

a vector with the coefficients corresponding to `object`.

## SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

## Author(s)

José Pinheiro and Douglas Bates

## Examples

```
coef(pdSymm(diag(3)))
```

---

coef.reStruct *reStruct Object Coefficients*

---

## Description

This method function extracts the coefficients associated with the positive-definite matrix represented by object.

## Usage

```
## S3 method for class 'reStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'reStruct'
coef(object, ...) <- value
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects. |
| unconstrained | a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE. |
| value | a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of coef(object) and must be given in unconstrained form. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

## Value

a vector with the coefficients corresponding to object.

## SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

coef.pdMat, reStruct, pdMat

## Examples

```
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
  B = pdDiag(2 * diag(4), form = ~Educ)))
coef(rs1)
```

---

`coef.varFunc` *varFunc Object Coefficients*

---

## Description

This method function extracts the coefficients associated with the variance function structure represented by `object`.

## Usage

```
## S3 method for class 'varFunc'
coef(object, unconstrained, allCoef, ...)
## S3 replacement method for class 'varIdent'
coef(object, ...) <- value
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`varFunc`" representing a variance function structure. |
| `unconstrained` | a logical value. If `TRUE` the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If `FALSE` the coefficients are returned in "natural", generally constrained form. Defaults to `TRUE`. |
| `allCoef` | a logical value. If `FALSE` only the coefficients which may vary during the optimization are returned. If `TRUE` all coefficients are returned. Defaults to `FALSE`. |
| `value` | a vector with the replacement values for the coefficients associated with `object`. It must be have the same length of `coef{object}` and must be given in unconstrained form. `Object` must be initialized before new values can be assigned to its coefficients. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

a vector with the coefficients corresponding to `object`.

## SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

## Author(s)

José Pinheiro and Douglas Bates

vf1 <- varPower(1)
coef(vf1)

coef(vf1) <- 2
```

---

`collapse` *Collapse According to Groups*

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Currently, only a `groupedData` method is available.

## Usage

```
collapse(object, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object to be collapsed, usually a data frame. |
| `...` | some methods for the generic may require additional arguments. |

## Value

will depend on the method function used; see the appropriate documentation.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

`collapse.groupedData`

## Examples

```
## see the method function documentation
```

## collapse.groupedData *Collapse a groupedData Object*

### Description

If object has a single grouping factor, it is returned unchanged. Else, it is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor.

### Usage

```
## S3 method for class 'groupedData'
collapse(object, collapseLevel, displayLevel,
       outer, inner, preserve, FUN, subset, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class groupedData, generally with multiple grouping factors. |
| collapseLevel | an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping. |
| displayLevel | an optional positive integer or character string indicating the grouping level to use as the grouping factor for the collapsed data. Default is collapseLevel. |
| outer | an optional logical value or one-sided formula, indicating covariates that are outer to the displayLevel grouping factor. If equal to TRUE, the displayLevel element attr(object, "outer") is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used. |
| inner | an optional logical value or one-sided formula, indicating a covariate that is inner to the displayLevel grouping factor. If equal to TRUE, attr(object, "outer") is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present. |
| preserve | an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the collapseLevel grouping factor. The collapsing factor is obtained by pasting together the levels of the collapseLevel grouping factor and the values of the covariate to be preserved. Default is NULL, meaning that no covariates need to be preserved. |
| FUN | an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by collapseLevel. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables |

in the data such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

subset — an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be preserved in the collapsed data. Default is NULL, meaning that all levels are used.

... — some methods for this generic require additional arguments. None are used in this method.

## Value

a groupedData object with a single grouping factor given by the displayLevel grouping factor, resulting from collapsing object over the levels of the collapseLevel grouping factor.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

groupedData, plot.nmGroupedData

## Examples

```
# collapsing by Dog
collapse(Pixel, collapse = 1)  # same as collapse(Pixel, collapse = "Dog")
```

---

# compareFits — *Compare Fitted Objects*

---

## Description

The columns in object1 and object2 are put together in matrices which allow direct comparison of the individual elements for each object. Missing columns in either object are replaced by NAs.

## Usage

```
compareFits(object1, object2, which)
```

## Arguments

object1,object2 — data frames, or matrices, with the same row names, but possibly different column names. These will usually correspond to coefficients from fitted objects with a grouping structure (e.g. lme and lmList objects).

which — an optional integer or character vector indicating which columns in object1 and object2 are to be used in the returned object. Defaults to all columns.

### Value

a three-dimensional array, with the third dimension given by the number of unique column names in either `object1` or `object2`. To each column name there corresponds a matrix with as many rows as the rows in `object1` and two columns, corresponding to `object1` and `object2`. The returned object inherits from class `compareFits`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`plot.compareFits`, `pairs.compareFits`, `comparePred`, `coef`, `random.effects`

### Examples

```
fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
compareFits(coef(fm1), coef(fm2))
```

---

## comparePred *Compare Predictions*

---

### Description

Predicted values are obtained at the specified values of `primary` for each object. If either `object1` or `object2` have a grouping structure (i.e. `getGroups(object)` is not `NULL`), predicted values are obtained for each group. When both objects determine groups, the group levels must be the same. If other covariates besides `primary` are used in the prediction model, their group-wise averages (numeric covariates) or most frequent values (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

### Usage

```
comparePred(object1, object2, primary, minimum, maximum,
    length.out, level, ...)
```

### Arguments

`object1,object2`
: fitted model objects, from which predictions can be extracted using the `predict` method.

`primary`
: an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate the objects (using `getCovariate`), it will be used as `primary`.

`minimum`
: an optional lower limit for the primary covariate. Defaults to `min(primary)`, after `primary` is evaluated in the `data` used in fitting `object1`.

`maximum`
: an optional upper limit for the primary covariate. Defaults to `max(primary)`, after `primary` is evaluated in the `data` used in fitting `object1`.

| | |
|---|---|
| `length.out` | an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51. |
| `level` | an optional integer specifying the desired prediction level. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Only one level can be specified. Defaults to the innermost level. |
| `...` | some methods for the generic may require additional arguments. |

## Value

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if `object` does not have a grouping structure, all elements will be `1`), the predicted or observed values, and the type of value in the third column: the objects' names are used to classify the predicted values and `original` is used for the observed values. The returned object inherits from classes `comparePred` and `augPred`.

## Note

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

`augPred`, `getGroups`

## Examples

```
fm1 <- lme(distance ~ age * Sex, data = Orthodont, random = ~ age)
fm2 <- update(fm1, distance ~ age)
comparePred(fm1, fm2, length.out = 2)
```

---

`corAR1` *AR(1) Correlation Structure*

---

## Description

This function is a constructor for the `corAR1` class, representing an autocorrelation structure of order 1. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

## Usage

```
corAR1(value, form, fixed)
```

## Arguments

| | |
|---|---|
| value | the value of the lag 1 autocorrelation, which must be between -1 and 1. Defaults to 0 (no autocorrelation). |
| form | a one sided formula of the form ~ t, or ~ t \| g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary. |

## Value

an object of class corAR1, representing an autocorrelation structure of order 1.

```

---

corARMA *ARMA(p,q) Correlation Structure*

---

## Description

This function is a constructor for the `corARMA` class, representing an autocorrelation-moving average correlation structure of order (p, q). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

## Usage

```
corARMA(value, form, p, q, fixed)
```

## Arguments

| | |
|---|---|
| `value` | a vector with the values of the autoregressive and moving average parameters, which must have length `p + q` and all elements between -1 and 1. Defaults to a vector of zeros, corresponding to uncorrelated observations. |
| `form` | a one sided formula of the form `~ t`, or `~ t \| g`, specifying a time covariate `t` and, optionally, a grouping factor `g`. A covariate for this correlation structure must be integer valued. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to `~ 1`, which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| `p, q` | non-negative integers specifying respectively the autoregressive order and the moving average order of the `ARMA` structure. Both default to 0. |
| `fixed` | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary. |

## Value

an object of class corARMA, representing an autocorrelation-moving average correlation structure.

corCAR1 *Continuous AR(1) Correlation Structure*

## Description

This function is a constructor for the corCAR1 class, representing an autocorrelation structure of order 1, with a continuous time covariate. Objects created using this constructor must be later initialized using the appropriate Initialize method.

## Usage

```
corCAR1(value, form, fixed)
```

## Arguments

| | |
|---|---|
| value | the correlation between two observations one unit of time apart. Must be between 0 and 1. Defaults to 0.2. |
| form | a one sided formula of the form ~ t, or ~ t \| g, specifying a time covariate t and, optionally, a grouping factor g. Covariates for this correlation structure need not be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary. |

## Value

an object of class corCAR1, representing an autocorrelation structure of order 1, with a continuous time covariate.

          correlation = corCAR1(form = ~Time))
```

---

`corClasses` *Correlation Structure Classes*

---

## Description

Standard classes of correlation structures (`corStruct`) available in the `nlme` package.

## Value

Available standard classes:

| | |
|---|---|
| `corAR1` | autoregressive process of order 1. |
| `corARMA` | autoregressive moving average process, with arbitrary orders for the autoregressive and moving average components. |
| `corCAR1` | continuous autoregressive process (AR(1) process for a continuous time covariate). |
| `corCompSymm` | compound symmetry structure corresponding to a constant correlation. |
| `corExp` | exponential spatial correlation. |
| `corGaus` | Gaussian spatial correlation. |
| `corLin` | linear spatial correlation. |
| `corRatio` | Rational quadratics spatial correlation. |
| `corSpher` | spherical spatial correlation. |
| `corSymm` | general correlation matrix, with no additional structure. |

## Note

Users may define their own `corStruct` classes by specifying a `constructor` function and, at a minimum, methods for the functions `corMatrix` and `coef`. For examples of these functions, see the methods for classes `corSymm` and `corAR1`.

corCompSymm *Compound Symmetry Correlation Structure*

---

## Description

This function is a constructor for the corCompSymm class, representing a compound symmetry structure corresponding to uniform correlation. Objects created using this constructor must later be initialized using the appropriate Initialize method.

## Usage

```
corCompSymm(value, form, fixed)
```

## Arguments

| | |
|---|---|
| value | the correlation between any two correlated observations. Defaults to 0. |
| form | a one sided formula of the form ~ t, or ~ t \| g, specifying a time covariate t and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary. |

## Value

an object of class corCompSymm, representing a compound symmetry correlation structure.

cs1CompSymm <- Initialize(cs1CompSymm, data = Orthodont)
corMatrix(cs1CompSymm)
```

---

`corExp` *Exponential Correlation Structure*

---

## Description

This function is a constructor for the `"corExp"` class, representing an exponential spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r$ apart is $\exp(-r/d)$ when no nugget effect is present and $(1-n)\exp(-r/d)$ when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

## Usage

```
corExp(value, form, nugget, metric, fixed)
```

## Arguments

| | |
|---|---|
| `value` | an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the exponential correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when `object` is initialized. |
| `form` | a one sided formula of the form `~ S1+...+Sp`, or `~ S1+...+Sp \| g`, specifying spatial covariates `S1` through `Sp` and, optionally, a grouping factor `g`. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to `~ 1`, which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| `nugget` | an optional logical value indicating whether a nugget effect is present. Defaults to `FALSE`. |

metric — an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed — an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

## Value

an object of class "corExp", also inheriting from class "corSpatial", representing an exponential spatial correlation structure.

`corFactor` *Factor of a Correlation Matrix*

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all `corStruct` classes.

## Usage

```
corFactor(object, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object from which a correlation matrix can be extracted. |
| `...` | some methods for this generic function require additional arguments. |

## Value

will depend on the method function used; see the appropriate documentation.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

`corFactor.corStruct`, `recalc.corStruct`

## Examples

```
## see the method function documentation
```

## corFactor.corStruct *Factor of a corStruct Object Matrix*

### Description

This method function extracts a transpose inverse square-root factor, or a series of transpose inverse square-root factors, of the correlation matrix, or list of correlation matrices, represented by `object`. Letting $\Sigma$ denote a correlation matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L'L$. This method extracts $L^{-t}$.

### Usage

```
## S3 method for class 'corStruct'
corFactor(object, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`corStruct`" representing a correlation structure, which must have been initialized (using `Initialize`). |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

If the correlation structure does not include a grouping factor, the returned value will be a vector with a transpose inverse square-root factor of the correlation matrix associated with `object` stacked column-wise. If the correlation structure includes a grouping factor, the returned value will be a vector with transpose inverse square-root factors of the correlation matrices for each group, stacked by group and stacked column-wise within each group.

### Note

This method function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `corMatrix` method function can be used to obtain transpose inverse square-root factors in matrix form.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### Examples

```
cs1 <- corAR1(form = ~1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
corFactor(cs1)
```

corGaus *Gaussian Correlation Structure*

## Description

This function is a constructor for the corGaus class, representing a Gaussian spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r$ apart is $\exp(-(r/d)^2)$ when no nugget effect is present and $(1-n)\exp(-(r/d)^2)$ when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate ‘ Initialize method.

## Usage

```
corGaus(value, form, nugget, metric, fixed)
```

## Arguments

| | |
|---|---|
| value | an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the Gaussian correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form | a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp \| g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE. |
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean". |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary. |

## Value

an object of class corGaus, also inheriting from class corSpatial, representing a Gaussian spatial correlation structure.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

fm1BW.lme <- lme(weight ~ Time * Diet, BodyWeight,
                 random = ~ Time)
# p. 223
fm2BW.lme <- update(fm1BW.lme, weights = varPower())
# p 246
fm3BW.lme <- update(fm2BW.lme,
          correlation = corExp(form = ~ Time))
# p. 249
fm8BW.lme <- update(fm3BW.lme, correlation = corGaus(form = ~ Time))
```

---

corLin *Linear Correlation Structure*

---

## Description

This function is a constructor for the corLin class, representing a linear spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r < d$ apart is $1 - (r/d)$ when no nugget effect is present and $(1 - n)(1 - (r/d))$ when a nugget effect is assumed. If $r \geq d$ the correlation is zero. Objects created using this constructor must later be initialized using the appropriate Initialize method.

## Usage

```
corLin(value, form, nugget, metric, fixed)
```

## Arguments

`value` an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the linear correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when `object` is initialized.

`form` a one sided formula of the form `~ S1+...+Sp`, or `~ S1+...+Sp | g`, specifying spatial covariates `S1` through `Sp` and, optionally, a grouping factor `g`. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to `~ 1`, which corresponds to using the order of the observations in the data as a covariate, and no groups.

`nugget` an optional logical value indicating whether a nugget effect is present. Defaults to `FALSE`.

`metric` an optional character string specifying the distance metric to be used. The currently available options are `"euclidean"` for the root sum-of-squares of distances; `"maximum"` for the maximum difference; and `"manhattan"` for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to `"euclidean"`.

`fixed` an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

## Value

an object of class `corLin`, also inheriting from class `corSpatial`, representing a linear spatial correlation structure.

```

## corMatrix.corStruct *Matrix of a corStruct Object*

### Description

This method function extracts the correlation matrix (or its transpose inverse square-root factor), or list of correlation matrices (or their transpose inverse square-root factors) corresponding to `covariate` and `object`. Letting $\Sigma$ denote a correlation matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L'L$. When `corr = FALSE`, this method extracts $L^{-t}$.

### Usage

```
## S3 method for class 'corStruct'
corMatrix(object, covariate, corr, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`corStruct`" representing a correlation structure. |
| `covariate` | an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to `getCovariate(object)`. |
| `corr` | a logical value. If `TRUE` the function returns the correlation matrix, or list of correlation matrices, represented by `object`. If `FALSE` the function returns a transpose inverse square-root of the correlation matrix, or a list of transpose inverse square-root factors of the correlation matrices. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

If `covariate` is a vector (matrix), the returned value will be an array with the corresponding correlation matrix (or its transpose inverse square-root factor). If the `covariate` is a list of vectors (matrices), the returned value will be a list with the correlation matrices (or their transpose inverse square-root factors) corresponding to each component of `covariate`.

cs1Exp <- Initialize(cs1Exp, spatDat)
corMatrix(cs1Exp)
```

---

`corMatrix.pdMat` *Extract Correlation Matrix from a pdMat Object*

---

## Description

The correlation matrix corresponding to the positive-definite matrix represented by `object` is obtained.

## Usage

```
## S3 method for class 'pdMat'
corMatrix(object, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`pdMat`", representing a positive definite matrix. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

the correlation matrix corresponding to the positive-definite matrix represented by `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

as.matrix.pdMat, pdMatrix

### Examples

```
pd1 <- pdSymm(diag(1:4))
corMatrix(pd1)
```

---

## corMatrix.reStruct *Extract Correlation Matrix from Components of an reStruct Object*

---

### Description

This method function extracts the correlation matrices corresponding to the pdMat elements of object.

### Usage

```
## S3 method for class 'reStruct'
corMatrix(object, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

a list with components given by the correlation matrices corresponding to the elements of object.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

as.matrix.reStruct, corMatrix, reStruct, pdMat

### Examples

```
rs1 <- reStruct(pdSymm(diag(3), ~age+Sex, data = Orthodont))
corMatrix(rs1)
```

corNatural *General correlation in natural parameterization*

## Description

This function is a constructor for the corNatural class, representing a general correlation structure in the "natural" parameterization, which is described under pdNatural. Objects created using this constructor must later be initialized using the appropriate Initialize method.

## Usage

```
corNatural(value, form, fixed)
```

## Arguments

| | |
|---|---|
| value | an optional vector with the parameter values. Default is numeric(0), which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure). |
| form | a one sided formula of the form ~ t, or ~ t \| g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary. |

## Value

an object of class corNatural representing a general correlation structure.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

Initialize.corNatural, pdNatural, summary.corNatural

## Examples

```
## covariate is observation order and grouping factor is Subject
cs1 <- corNatural(form = ~ 1 | Subject)
```

corRatio *Rational Quadratic Correlation Structure*

## Description

This function is a constructor for the `corRatio` class, representing a rational quadratic spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r$ apart is $1/(1+(r/d)^2)$ when no nugget effect is present and $(1-n)/(1+(r/d)^2)$ when a nugget effect is assumed. Objects created using this constructor need to be later initialized using the appropriate `Initialize` method.

## Usage

```
corRatio(value, form, nugget, metric, fixed)
```

## Arguments

| | |
|---|---|
| `value` | an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the rational quadratic correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when `object` is initialized. |
| `form` | a one sided formula of the form `~ S1+...+Sp`, or `~ S1+...+Sp \| g`, specifying spatial covariates `S1` through `Sp` and, optionally, a grouping factor `g`. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to `~ 1`, which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| `nugget` | an optional logical value indicating whether a nugget effect is present. Defaults to `FALSE`. |
| `metric` | an optional character string specifying the distance metric to be used. The currently available options are `"euclidean"` for the root sum-of-squares of distances; `"maximum"` for the maximum difference; and `"manhattan"` for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to `"euclidean"`. |
| `fixed` | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary. |

## Value

an object of class `corRatio`, also inheriting from class `corSpatial`, representing a rational quadratic spatial correlation structure.

       form = ~ latitude + longitude,
             nugget = TRUE))
```

---

## corSpatial *Spatial Correlation Structure*

---

### Description

This function is a constructor for the corSpatial class, representing a spatial correlation structure. This class is "virtual", having four "real" classes, corresponding to specific spatial correlation structures, associated with it: corExp, corGaus, corLin, corRatio, and corSpher. The returned object will inherit from one of these "real" classes, determined by the type argument, and from the "virtual" corSpatial class. Objects created using this constructor must later be initialized using the appropriate Initialize method.

## Usage

```
corSpatial(value, form, nugget, type, metric, fixed)
```

## Arguments

| | |
|---|---|
| value | an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the spatial correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form | a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp \| g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE. |
| type | an optional character string specifying the desired type of correlation structure. Available types include "spherical", "exponential", "gaussian", "linear", and "rational". See the documentation on the functions corSpher, corExp, corGaus, corLin, and corRatio for a description of these correlation structures. Partial matching of arguments is used, so only the first character needs to be provided.Defaults to "spherical". |
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean". |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary. |

## Value

an object of class determined by the type argument and also inheriting from class corSpatial, representing a spatial correlation structure.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

## See Also

corExp, corGaus, corLin, corRatio, corSpher, Initialize.corStruct, summary.corStruct, dist

## Examples

```
sp1 <- corSpatial(form = ~ x + y + z, type = "g", metric = "man")
```

---

corSpher *Spherical Correlation Structure*

---

## Description

This function is a constructor for the corSpher class, representing a spherical spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r < d$ apart is $1-1.5(r/d)+0.5(r/d)^3$ when no nugget effect is present and $(1-n)(1-1.5(r/d)+0.5(r/d)^3)$ when a nugget effect is assumed. If $r \geq d$ the correlation is zero. Objects created using this constructor must later be initialized using the appropriate Initialize method.

## Usage

```
corSpher(value, form, nugget, metric, fixed)
```

## Arguments

| | |
|---|---|
| value | an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the spherical correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form | a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp \| g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE. |

`metric` an optional character string specifying the distance metric to be used. The currently available options are `"euclidean"` for the root sum-of-squares of distances; `"maximum"` for the maximum difference; and `"manhattan"` for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to `"euclidean"`.

`fixed` an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

## Value

an object of class `corSpher`, also inheriting from class `corSpatial`, representing a spherical spatial correlation structure.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

# p. 262
fm2Wheat2 <- update(fm1Wheat2, corr =
   corSpher(c(28, 0.2),
     form = ~ latitude + longitude, nugget = TRUE))
```

corSymm *General Correlation Structure*

## Description

This function is a constructor for the corSymm class, representing a general correlation structure. The internal representation of this structure, in terms of unconstrained parameters, uses the spherical parametrization defined in Pinheiro and Bates (1996). Objects created using this constructor must later be initialized using the appropriate Initialize method.

## Usage

```
corSymm(value, form, fixed)
```

## Arguments

| | |
|---|---|
| value | an optional vector with the parameter values. Default is numeric(0), which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure). |
| form | a one sided formula of the form ~ t, or ~ t \| g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary. |

## Value

an object of class corSymm representing a general correlation structure.

`Covariate` *Assign Covariate Values*

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "`varFunc`" classes.

## Usage

```
covariate(object) <- value
```

## Arguments

| | |
|---|---|
| `object` | any object with a `covariate` component. |
| `value` | a value to be assigned to the covariate associated with `object`. |

## Value

will depend on the method function; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

getCovariate

### Examples

```
## see the method function documentation
```

---

## Covariate.varFunc *Assign varFunc Covariate*

---

### Description

The covariate(s) used in the calculation of the weights of the variance function represented by object is (are) replaced by value. If object has been initialized, value must have the same dimensions as getCovariate(object).

### Usage

```
## S3 replacement method for class 'varFunc'
covariate(object) <- value
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "varFunc", representing a variance function structure. |
| value | a value to be assigned to the covariate associated with object. |

### Value

a varFunc object similar to object, but with its covariate attribute replaced by value.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

getCovariate.varFunc

### Examples

```
vf1 <- varPower(1.1, form = ~age)
covariate(vf1) <- Orthodont[["age"]]
```

## Dialyzer — *High-Flux Hemodialyzer*

### Description

The `Dialyzer` data frame has 140 rows and 5 columns.

### Format

This data frame contains the following columns:

**Subject** an ordered factor with levels `10` < `8` < `2` < `6` < `3` < `5` < `9` < `7` < `1` < `4` < `17` < `20` < `11` < `12` < `16` < `13` < `14` < `18` < `15` < `19` giving the unique identifier for each subject

**QB** a factor with levels `200` and `300` giving the bovine blood flow rate (dL/min).

**pressure** a numeric vector giving the transmembrane pressure (dmHg).

**rate** the hemodialyzer ultrafiltration rate (mL/hr).

**index** index of observation within subject—1 through 7.

### Details

Vonesh and Carter (1992) describe data measured on high-flux hemodialyzers to assess their *in vivo* ultrafiltration characteristics. The ultrafiltration rates (in mL/hr) of 20 high-flux dialyzers were measured at seven different transmembrane pressures (in dmHg). The *in vitro* evaluation of the dialyzers used bovine blood at flow rates of either 200~dl/min or 300~dl/min. The data, are also analyzed in Littell, Milliken, Stroup, and Wolfinger (1996).

## Dim — *Extract Dimensions from an Object*

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `"corSpatial"`, `"corStruct"`, `"pdCompSymm"`, `"pdDiag"`, `"pdIdent"`, `"pdMat"`, and `"pdSymm"`.

### Usage

```
Dim(object, ...)
```

### Arguments

| | |
|---|---|
| `object` | any object for which dimensions can be extracted. |
| `...` | some methods for this generic function require additional arguments. |

### Value

will depend on the method function used; see the appropriate documentation.

### Note

If `dim` allowed more than one argument, there would be no need for this generic function.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`Dim.pdMat`, `Dim.corStruct`

### Examples

```
## see the method function documentation
```

---

## Dim.corSpatial *Dimensions of a corSpatial Object*

---

### Description

if `groups` is missing, it returns the `Dim` attribute of `object`; otherwise, calculates the dimensions associated with the grouping factor.

### Usage

```
## S3 method for class 'corSpatial'
Dim(object, groups, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`corSpatial`", representing a spatial correlation structure. |
| `groups` | an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated. |
| `...` | further arguments to be passed to or from methods. |

### Value

a list with components:

| | |
|---|---|
| N | length of groups |
| M | number of groups |
| spClass | an integer representing the spatial correlation class; 0 = user defined class, 1 = corSpher, 2 = corExp, 3 = corGaus, 4 = corLin |
| sumLenSq | sum of the squares of the number of observations per group |
| len | an integer vector with the number of observations per group |
| start | an integer vector with the starting position for the distance vectors in each group, beginning from zero |

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

Dim, Dim.corStruct

### Examples

```
Dim(corGaus(), getGroups(Orthodont))

cs1ARMA <- corARMA(0.4, form = ~ 1 | Subject, q = 1)
cs1ARMA <- Initialize(cs1ARMA, data = Orthodont)
Dim(cs1ARMA)
```

---

## Dim.corStruct *Dimensions of a corStruct Object*

---

### Description

if groups is missing, it returns the Dim attribute of object; otherwise, calculates the dimensions associated with the grouping factor.

### Usage

```
## S3 method for class 'corStruct'
Dim(object, groups, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "corStruct", representing a correlation structure. |
| groups | an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

a list with components:

| | |
|---|---|
| N | length of groups |
| M | number of groups |
| maxLen | maximum number of observations in a group |
| sumLenSq | sum of the squares of the number of observations per group |
| len | an integer vector with the number of observations per group |
| start | an integer vector with the starting position for the observations in each group, beginning from zero |

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

Dim, Dim.corSpatial

### Examples

```
Dim(corAR1(), getGroups(Orthodont))
```

---

## Dim.pdMat *Dimensions of a pdMat Object*

---

### Description

This method function returns the dimensions of the matrix represented by object.

### Usage

```
## S3 method for class 'pdMat'
Dim(object, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "pdMat", representing a positive-definite matrix. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

an integer vector with the number of rows and columns of the matrix represented by object.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

Dim

## Examples

```
Dim(pdSymm(diag(3)))
```

---

Earthquake *Earthquake Intensity*

---

## Description

The Earthquake data frame has 182 rows and 5 columns.

## Format

This data frame contains the following columns:

**Quake** an ordered factor with levels 20 < 16 < 14 < 10 < 3 < 8 < 23 < 22 < 6 < 13 < 7 < 21 < 18 < 15 < 4 < 12 < 19 < 5 < 9 < 1 < 2 < 17 < 11 indicating the earthquake on which the measurements were made.

**Richter** a numeric vector giving the intensity of the earthquake on the Richter scale.

**distance** the distance from the seismological measuring station to the epicenter of the earthquake (km).

**soil** a factor with levels 0 and 1 giving the soil condition at the measuring station, either soil or rock.

**accel** maximum horizontal acceleration observed (g).

## Details

Measurements recorded at available seismometer locations for 23 large earthquakes in western North America between 1940 and 1980. They were originally given in Joyner and Boore (1981); are mentioned in Brillinger (1987); and are analyzed in Davidian and Giltinan (1995).

## ergoStool — *Ergometrics experiment with stool types*

### Description

The `ergoStool` data frame has 36 rows and 3 columns.

### Format

This data frame contains the following columns:

**effort** a numeric vector giving the effort (Borg scale) required to arise from a stool.

**Type** a factor with levels `T1`, `T2`, `T3`, and `T4` giving the stool type.

**Subject** an ordered factor giving a unique identifier for the subject in the experiment.

### Details

Devore (2000) cites data from an article in *Ergometrics* (1993, pp. 519-535) on "The Effects of a Pneumatic Stool and a One-Legged Stool on Lower Limb Joint Load and Muscular Activity."

### Examples

```
fm1 <-
   lme(effort ~ Type, data = ergoStool, random = ~ 1 | Subject)
anova( fm1 )
```

## Fatigue — *Cracks caused by metal fatigue*

### Description

The `Fatigue` data frame has 262 rows and 3 columns.

### Format

This data frame contains the following columns:

**Path** an ordered factor with levels `1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9 < 10 < 11 < 12 < 13 < 14 < 15 < 16 < 17 < 18 < 19 < 20 < 21` giving the test path (or test unit) number. The order is in terms of increasing failure time or decreasing terminal crack length.

**cycles** number of test cycles at which the measurement is made (millions of cycles).

**relLength** relative crack length (dimensionless).

## Details

These data are given in Lu and Meeker (1993) where they state "We obtained the data in Table 1 visually from figure 4.5.2 on page 242 of Bogdanoff and Kozin (1985)." The data represent the growth of cracks in metal for 21 test units. An initial notch of length 0.90 inches was made on each unit which then was subjected to several thousand test cycles. After every 10,000 test cycles the crack length was measured. Testing was stopped if the crack length exceeded 1.60 inches, defined as a failure, or at 120,000 cycles.

---

`fdHess` *Finite difference Hessian*

---

## Description

Evaluate an approximate Hessian and gradient of a scalar function using finite differences.

## Usage

```
fdHess(pars, fun, ...,
       .relStep = .Machine$double.eps^(1/3), minAbsPar = 0)
```

## Arguments

| | |
|---|---|
| `pars` | the numeric values of the parameters at which to evaluate the function `fun` and its derivatives. |
| `fun` | a function depending on the parameters `pars` that returns a numeric scalar. |
| `...` | Optional additional arguments to `fun` |
| `.relStep` | The relative step size to use in the finite differences. It defaults to the cube root of `.Machine$double.eps` |
| `minAbsPar` | The minimum magnitude of a parameter value that is considered non-zero. It defaults to zero meaning that any non-zero value will be considered different from zero. |

## Details

This function uses a second-order response surface design known as a "Koschal design" to determine the parameter values at which the function is evaluated.

## Value

A list with components

| | |
|---|---|
| `mean` | the value of function `fun` evaluated at the parameter values `pars` |
| `gradient` | an approximate gradient (of length `length(pars)`). |
| `Hessian` | a matrix whose upper triangle contains an approximate Hessian. |

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### Examples

```
(fdH <- fdHess(c(12.3, 2.34), function(x) x[1]*(1-exp(-0.4*x[2]))))
stopifnot(length(fdH$ mean) == 1,
          length(fdH$ gradient) == 2,
          identical(dim(fdH$ Hessian), c(2L, 2L)))
```

---

## fitted.glsStruct *Calculate glsStruct Fitted Values*

---

### Description

The fitted values for the linear model represented by `object` are extracted.

### Usage

```
## S3 method for class 'glsStruct'
fitted(object, glsFit, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`glsStruct`", representing a list of linear model components, such as `corStruct` and "`varFunc`" objects. |
| `glsFit` | an optional list with components `logLik` (log-likelihood), `beta` (coefficients), `sigma` (standard deviation for error term), `varBeta` (coefficients' covariance matrix), `fitted` (fitted values), and `residuals` (residuals). Defaults to `attr(object, "glsFit")`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

a vector with the fitted values for the linear model represented by `object`.

### Note

This method function is generally only used inside `gls` and `fitted.gls`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`gls`, `residuals.glsStruct`

## fitted.gnlsStruct — *Calculate gnlsStruct Fitted Values*

### Description

The fitted values for the nonlinear model represented by `object` are extracted.

### Usage

```
## S3 method for class 'gnlsStruct'
fitted(object, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`gnlsStruct`", representing a list of model components, such as `corStruct` and `varFunc` objects, and attributes specifying the underlying nonlinear model and the response variable. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

a vector with the fitted values for the nonlinear model represented by `object`.

### Note

This method function is generally only used inside `gnls` and `fitted.gnls`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`gnls`, `residuals.gnlsStruct`

## fitted.lme — *Extract lme Fitted Values*

### Description

The fitted values at level $i$ are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to $i$. The resulting values estimate the best linear unbiased predictions (BLUPs) at level $i$.

### Usage

```
## S3 method for class 'lme'
fitted(object, level, asList, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`lme`", representing a fitted linear mixed-effects model. |
| `level` | an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping. |
| `asList` | an optional logical value. If `TRUE` and a single value is given in `level`, the returned object is a list with the fitted values split by groups; else the returned value is either a vector or a data frame, according to the length of `level`. Defaults to `FALSE`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

If a single level of grouping is specified in `level`, the returned value is either a list with the fitted values split by groups (`asList = TRUE`) or a vector with the fitted values (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the fitted values at different levels and the grouping factors. For a vector or data frame result the `napredict` method is applied.

---

## `fitted.lmeStruct` *Calculate lmeStruct Fitted Values*

---

### Description

The fitted values at level $i$ are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to $i$. The resulting values estimate the best linear unbiased predictions (BLUPs) at level $i$.

### Usage

```
## S3 method for class 'lmeStruct'
fitted(object, level, conLin, lmeFit, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`lmeStruct`", representing a list of linear mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects. |
| `level` | an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping. |
| `conLin` | an optional condensed linear model object, consisting of a list with components "`Xy`", corresponding to a regression matrix (`X`) combined with a response vector (`y`), and "`logLik`", corresponding to the log-likelihood of the underlying lme model. Defaults to `attr(object, "conLin")`. |
| `lmeFit` | an optional list with components `beta` and `b` containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the fitted values. Defaults to `attr(object, "lmeFit")`. |
| `...` | some methods for this generic accept other optional arguments. |

### Value

if a single level of grouping is specified in `level`, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the fitted values at different levels.

### Note

This method function is generally only used inside `lme` and `fitted.lme`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lme`, `fitted.lme`, `residuals.lmeStruct`

---

## `fitted.lmList` *Extract lmList Fitted Values*

---

### Description

The fitted values are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

### Usage

```
## S3 method for class 'lmList'
fitted(object, subset, asList, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "lmList", representing a list of lm objects with a common model. |
| subset | an optional character or integer vector naming the lm components of object from which the fitted values are to be extracted. Default is NULL, in which case all components are used. |
| asList | an optional logical value. If TRUE, the returned object is a list with the fitted values split by groups; else the returned value is a vector. Defaults to FALSE. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

a list with components given by the fitted values of each lm component of object, or a vector with the fitted values for all lm components of object.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

lmList, residuals.lmList

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
fitted(fm1)
```

---

## fitted.nlmeStruct *Calculate nlmeStruct Fitted Values*

---

### Description

The fitted values at level $i$ are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to $i$ and evaluating the model function at the resulting estimated parameters. The resulting values estimate the predictions at level $i$.

### Usage

```
## S3 method for class 'nlmeStruct'
fitted(object, level, conLin, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"nlmeStruct"`, representing a list of mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects, plus attributes specifying the underlying nonlinear model and the response variable. |
| `level` | an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping. |
| `conLin` | an optional condensed linear model object, consisting of a list with components `"Xy"`, corresponding to a regression matrix (`X`) combined with a response vector (`y`), and `"logLik"`, corresponding to the log-likelihood of the underlying nlme model. Defaults to `attr(object, "conLin")`. |
| `...` | additional arguments that could be given to this method. None are used. |

### Value

if a single level of grouping is specified in `level`, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the fitted values at different levels.

### Note

This method function is generally only used inside `nlme` and `fitted.nlme`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

---

## `fixed.effects` *Extract Fixed Effects*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmList` and `lme`.

### Usage

```
fixed.effects(object, ...)
fixef(object, ...)
```

### Arguments

| | |
|---|---|
| `object` | any fitted model object from which fixed effects estimates can be extracted. |
| `...` | some methods for this generic function require additional arguments. |

### Value

will depend on the method function used; see the appropriate documentation.

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

### See Also

`fixef.lmList`

### Examples

```
## see the method function documentation
```

---

## `fixef.lmList` *Extract lmList Fixed Effects*

---

### Description

The average of the coefficients corresponding to the `lm` components of `object` is calculated.

### Usage

```
## S3 method for class 'lmList'
fixef(object, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`lmList`", representing a list of `lm` objects with a common model. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

a vector with the average of the individual `lm` coefficients in `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lmList`, `random.effects.lmList`

## Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
fixed.effects(fm1)
```

---

`formula.pdBlocked` *Extract pdBlocked Formula*

---

## Description

The `formula` attributes of the `pdMat` elements of `x` are extracted and returned as a list, in case `asList=TRUE`, or converted to a single one-sided formula when `asList=FALSE`. If the `pdMat` elements do not have a `formula` attribute, a `NULL` value is returned.

## Usage

```
## S3 method for class 'pdBlocked'
formula(x, asList, ...)
```

## Arguments

| | |
|---|---|
| `x` | an object inheriting from class `"pdBlocked"`, representing a positive definite block diagonal matrix. |
| `asList` | an optional logical value. If `TRUE`, a list with the formulas for the individual block diagonal elements of `x` is returned; else, if `FALSE`, a one-sided formula combining all individual formulas is returned. Defaults to `FALSE`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

a list of one-sided formulas, or a single one-sided formula, or `NULL`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

`pdBlocked`, `pdMat`

## Examples

```
pd1 <- pdBlocked(list(~ age, ~ Sex - 1))
formula(pd1)
formula(pd1, asList = TRUE)
```

formula.pdMat *Extract pdMat Formula*

## Description

This method function extracts the formula associated with a pdMat object, in which the column and row names are specified.

## Usage

```
## S3 method for class 'pdMat'
formula(x, asList, ...)
```

## Arguments

| | |
|---|---|
| x | an object inheriting from class "pdMat", representing a positive definite matrix. |
| asList | logical. Should the asList argument be applied to each of the components? Never used. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

## Value

if x has a formula attribute, its value is returned, else NULL is returned.

## Note

Because factors may be present in formula(x), the pdMat object needs to have access to a data frame where the variables named in the formula can be evaluated, before it can resolve its row and column names from the formula.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

pdMat

## Examples

```
pd1 <- pdSymm(~Sex*age)
formula(pd1)
```

## formula.reStruct — *Extract reStruct Object Formula*

### Description

This method function extracts a formula from each of the components of x, returning a list of formulas.

### Usage

```
## S3 method for class 'reStruct'
formula(x, asList, ...)
```

### Arguments

| | |
|---|---|
| x | an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects. |
| asList | logical. Should the asList argument be applied to each of the components? |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

a list with the formulas of each component of x.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

formula

### Examples

```
rs1 <- reStruct(list(A = pdDiag(diag(2), ~age), B = ~1))
formula(rs1)
```

## gapply — *Apply a Function by Groups*

### Description

Applies the function to the distinct sets of rows of the data frame defined by groups.

### Usage

```
gapply(object, which, FUN, form, level, groups, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object to which the function will be applied - usually a `groupedData` object or a `data.frame`. Must inherit from class `"data.frame"`. |
| `which` | an optional character or positive integer vector specifying which columns of `object` should be used with `FUN`. Defaults to all columns in `object`. |
| `FUN` | function to apply to the distinct sets of rows of the data frame `object` defined by the values of `groups`. |
| `form` | an optional one-sided formula that defines the groups. When this formula is given the right-hand side is evaluated in `object`, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to `formula(object)`. |
| `level` | an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping. |
| `groups` | an optional factor that will be used to split the rows into groups. Defaults to `getGroups(object, form, level)`. |
| `...` | optional additional arguments to the summary function `FUN`. Often it is helpful to specify `na.rm = TRUE`. |

## Value

Returns a data frame with as many rows as there are levels in the `groups` argument.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. sec. 3.4.

## See Also

`gsummary`

## Examples

```
## Find number of non-missing "conc" observations for each Subject
gapply( Phenobarb, FUN = function(x) sum(!is.na(x$conc)) )

# Pinheiro and Bates, p. 127
table( gapply(Quinidine, "conc", function(x) sum(!is.na(x))) )
changeRecords <- gapply( Quinidine, FUN = function(frm)
    any(is.na(frm[["conc"]]) & is.na(frm[["dose"]])) )
```

## Gasoline — *Refinery yield of gasoline*

### Description

The `Gasoline` data frame has 32 rows and 6 columns.

### Format

This data frame contains the following columns:

**yield** a numeric vector giving the percentage of crude oil converted to gasoline after distillation and fractionation

**endpoint** a numeric vector giving the temperature (degrees F) at which all the gasoline is vaporized

**Sample** an ordered factor giving the inferred crude oil sample number

**API** a numeric vector giving the crude oil gravity (degrees API)

**vapor** a numeric vector giving the vapor pressure of the crude oil $(\mathrm{lbf}/\mathrm{in}^2)$

**ASTM** a numeric vector giving the crude oil 10% point ASTM—the temperature at which 10% of the crude oil has become vapor.

### Details

Prater (1955) provides data on crude oil properties and gasoline yields. Atkinson (1985) uses these data to illustrate the use of diagnostics in multiple regression analysis. Three of the covariates—`API`, `vapor`, and `ASTM`—measure characteristics of the crude oil used to produce the gasoline. The other covariate — `endpoint`—is a characteristic of the refining process. Daniel and Wood (1980) notice that the covariates characterizing the crude oil occur in only ten distinct groups and conclude that the data represent responses measured on ten different crude oil samples.

## getCovariate — *Extract Covariate from an Object*

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `corStruct`, `corSpatial`, `data.frame`, and `varFunc`.

### Usage

```
getCovariate(object, form, data)
```

### Arguments

| | |
|---|---|
| object | any object with a covariate component |
| form | an optional one-sided formula specifying the covariate(s) to be extracted. Defaults to formula(object). |
| data | a data frame in which to evaluate the variables defined in form. |

### Value

will depend on the method function used; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. p. 100.

### See Also

getCovariate.corStruct, getCovariate.data.frame, getCovariate.varFunc, getCovariateFormula

### Examples

```
## see the method function documentation
```

---

## getCovariate.corStruct

*Extract corStruct Object Covariate*

---

### Description

This method function extracts the covariate(s) associated with object.

### Usage

```
## S3 method for class 'corStruct'
getCovariate(object, form, data)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class corStruct representing a correlation structure. |
| form | this argument is included to make the method function compatible with the generic. It will be assigned the value of formula(object) and should not be modified. |
| data | an optional data frame in which to evaluate the variables defined in form, in case object is not initialized and the covariate needs to be evaluated. |

### Value

when the correlation structure does not include a grouping factor, the returned value will be a vector or a matrix with the covariate(s) associated with `object`. If a grouping factor is present, the returned value will be a list of vectors or matrices with the covariate(s) corresponding to each grouping level.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

### See Also

`getCovariate`

### Examples

```
cs1 <- corAR1(form = ~ 1 | Subject)
getCovariate(cs1, data = Orthodont)
```

---

## getCovariate.data.frame

*Extract Data Frame Covariate*

---

### Description

The right hand side of `form`, stripped of any conditioning expression (i.e. an expression following a `|` operator), is evaluated in `object`.

### Usage

```
## S3 method for class 'data.frame'
getCovariate(object, form, data)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `data.frame`. |
| `form` | an optional formula specifying the covariate to be evaluated in `object`. Defaults to `formula(object)`. |
| `data` | some methods for this generic require a separate data frame. Not used in this method. |

### Value

the value of the right hand side of `form`, stripped of any conditional expression, evaluated in `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

getCovariateFormula

### Examples

```
getCovariate(Orthodont)
```

---

## getCovariate.varFunc *Extract varFunc Covariate*

---

### Description

This method function extracts the covariate(s) associated with the variance function represented by `object`, if any is present.

### Usage

```
## S3 method for class 'varFunc'
getCovariate(object, form, data)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `varFunc`, representing a variance function structure. |
| `form` | an optional formula specifying the covariate to be evaluated in `object`. Defaults to `formula(object)`. |
| `data` | some methods for this generic require a `data` object. Not used in this method. |

### Value

if `object` has a `covariate` attribute, its value is returned; else `NULL` is returned.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

covariate<-.varFunc

### Examples

```
vf1 <- varPower(1.1, form = ~age)
covariate(vf1) <- Orthodont[["age"]]
getCovariate(vf1)
```

## getCovariateFormula *Extract Covariates Formula*

### Description

The right hand side of `formula(object)`, without any conditioning expressions (i.e. any expressions after a `|` operator) is returned as a one-sided formula.

### Usage

```
getCovariateFormula(object)
```

### Arguments

| | |
|---|---|
| `object` | any object from which a formula can be extracted. |

### Value

a one-sided formula describing the covariates associated with `formula(object)`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`getCovariate`

### Examples

```
getCovariateFormula(y ~ x | g)
getCovariateFormula(y ~ x)
```

## getData *Extract Data from an Object*

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `gls`, `lme`, and `lmList`.

### Usage

```
getData(object)
```

### Arguments

| | |
|---|---|
| `object` | an object from which a data.frame can be extracted, generally a fitted model object. |

### Value

will depend on the method function used; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

getData.gls, getData.lme, getData.lmList

### Examples

```
## see the method function documentation
```

---

## getData.gls *Extract gls Object Data*

---

### Description

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

### Usage

```
## S3 method for class 'gls'
getData(object)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class gls, representing a generalized least squares fitted linear model. |

### Value

if a data argument is present in the calling sequence that produced object, the corresponding data frame (with na.action and subset applied to it, if also present in the call that produced object) is returned; else, NULL is returned.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

gls, getData

### Examples

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
getData(fm1)
```

## getData.lme — *Extract lme Object Data*

### Description

If present in the calling sequence used to produce `object`, the data frame used to fit the model is obtained.

### Usage

```
## S3 method for class 'lme'
getData(object)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `lme`, representing a linear mixed-effects fitted model. |

### Value

if a `data` argument is present in the calling sequence that produced `object`, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced `object`) is returned; else, `NULL` is returned.

Note that as from version 3.1-102, this only omits rows omitted in the fit if `na.action = na.omit`, and does not omit at all if `na.action = na.exclude`. That is generally what is wanted for plotting, the main use of this function.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lme`, `getData`

### Examples

```
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,
           random = ~ sin(2*pi*Time))
getData(fm1)
```

## getData.lmList — *Extract lmList Object Data*

### Description

If present in the calling sequence used to produce `object`, the data frame used to fit the model is obtained.

### Usage

```
## S3 method for class 'lmList'
getData(object)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `lmList`, representing a list of `lm` objects with a common model. |

### Value

if a `data` argument is present in the calling sequence that produced `object`, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced `object`) is returned; else, `NULL` is returned.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lmList`, `getData`

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
getData(fm1)
```

## getGroups — *Extract Grouping Factors from an Object*

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `corStruct`, `data.frame`, `gls`, `lme`, `lmList`, and `varFunc`.

### Usage

```
getGroups(object, form, level, data, sep)
```

### Arguments

| | |
|---|---|
| `object` | any object |
| `form` | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the `|` operator). Defaults to `formula(object)`. |
| `level` | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. |
| `data` | a data frame in which to interpret the variables named in `form`. Optional for most methods. |
| `sep` | character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`. |

### Value

will depend on the method function used; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. pp. 100, 461.

### See Also

`getGroupsFormula`, `getGroups.data.frame`, `getGroups.gls`, `getGroups.lmList`, `getGroups.lme`

### Examples

```
## see the method function documentation
```

---

## `getGroups.corStruct` *Extract corStruct Groups*

---

### Description

This method function extracts the grouping factor associated with `object`, if any is present.

### Usage

```
## S3 method for class 'corStruct'
getGroups(object, form, level, data, sep)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `corStruct` representing a correlation structure. |
| `form` | this argument is included to make the method function compatible with the generic. It will be assigned the value of `formula(object)` and should not be modified. |
| `level` | this argument is included to make the method function compatible with the generic and is not used. |
| `data` | an optional data frame in which to evaluate the variables defined in `form`, in case `object` is not initialized and the grouping factor needs to be evaluated. |
| `sep` | character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`. |

### Value

if a grouping factor is present in the correlation structure represented by `object`, the function returns the corresponding factor vector; else the function returns `NULL`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`getGroups`

### Examples

```
cs1 <- corAR1(form = ~ 1 | Subject)
getGroups(cs1, data = Orthodont)
```

---

## `getGroups.data.frame` *Extract Groups from a Data Frame*

---

### Description

Each variable named in the expression after the `|` operator on the right hand side of `form` is evaluated in `object`. If more than one variable is indicated in `level` they are combined into a data frame; else the selected variable is returned as a vector. When multiple grouping levels are defined in `form` and `level > 1`, the levels of the returned factor are obtained by pasting together the levels of the grouping factors of level greater or equal to `level`, to ensure their uniqueness.

### Usage

```
## S3 method for class 'data.frame'
getGroups(object, form, level, data, sep)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `data.frame`. |
| `form` | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the `|` operator). Defaults to `formula(object)`. |
| `level` | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. Defaults to all levels of nesting. |
| `data` | unused |
| `sep` | character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`. |

### Value

either a data frame with columns given by the grouping factors indicated in `level`, from outer to inner, or, when a single level is requested, a factor representing the selected grouping factor.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. pp. 100, 461.

### See Also

`getGroupsFormula`

### Examples

```
getGroups(Pixel)
getGroups(Pixel, level = 2)
```

---

## getGroups.gls *Extract gls Object Groups*

---

### Description

If present, the grouping factor associated to the correlation structure for the linear model represented by `object` is extracted.

### Usage

```
## S3 method for class 'gls'
getGroups(object, form, level, data, sep)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `gls`, representing a generalized least squares fitted linear model. |
| `form` | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the `|` operator). Defaults to `formula(object)`. Not used. |
| `level` | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used. |
| `data` | a data frame in which to interpret the variables named in `form`. Optional for most methods. Not used. |
| `sep` | character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`. Not used. |

### Value

if the linear model represented by `object` incorporates a correlation structure and the corresponding `corStruct` object has a grouping factor, a vector with the group values is returned; else, `NULL` is returned.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`gls`, `corClasses`

### Examples

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
getGroups(fm1)
```

---

## `getGroups.lme` *Extract lme Object Groups*

---

### Description

The grouping factors corresponding to the linear mixed-effects model represented by `object` are extracted. If more than one level is indicated in `level`, the corresponding grouping factors are combined into a data frame; else the selected grouping factor is returned as a vector.

### Usage

```
## S3 method for class 'lme'
getGroups(object, form, level, data, sep)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `lme`, representing a fitted linear mixed-effects model. |
| `form` | this argument is included to make the method function compatible with the generic and is ignored in this method. |
| `level` | an optional integer vector giving the level(s) of grouping to be extracted from `object`. Defaults to the highest or innermost level of grouping. |
| `data` | unused |
| `sep` | character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`. |

### Value

either a data frame with columns given by the grouping factors indicated in `level`, or, when a single level is requested, a factor representing the selected grouping factor.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lme`

### Examples

```
fm1 <- lme(pixel ~ day + day^2, Pixel,
  random = list(Dog = ~day, Side = ~1))
getGroups(fm1, level = 1:2)
```

---

## `getGroups.lmList` *Extract lmList Object Groups*

---

### Description

The grouping factor determining the partitioning of the observations used to produce the `lm` components of `object` is extracted.

### Usage

```
## S3 method for class 'lmList'
getGroups(object, form, level, data, sep)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `lmList`, representing a list of `lm` objects with a common model. |
| `form` | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the `|` operator). Defaults to `formula(object)`. Not used. |
| `level` | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used. |
| `data` | a data frame in which to interpret the variables named in `form`. Optional for most methods. Not used. |
| `sep` | character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`. Not used. |

### Value

a vector with the grouping factor corresponding to the `lm` components of `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lmList`

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
getGroups(fm1)
```

---

## `getGroups.varFunc` *Extract varFunc Groups*

---

### Description

This method function extracts the grouping factor associated with the variance function represented by `object`, if any is present.

### Usage

```
## S3 method for class 'varFunc'
getGroups(object, form, level, data, sep)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class varFunc, representing a variance function structure. |
| form | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the \| operator). Defaults to formula(object). Not used. |
| level | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used. |
| data | a data frame in which to interpret the variables named in form. Optional for most methods. Not used. |
| sep | character, the separator to use between group levels when multiple levels are collapsed. The default is '/'. Not used. |

### Value

if object has a groups attribute, its value is returned; else NULL is returned.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### Examples

```
vf1 <- varPower(form = ~ age | Sex)
vf1 <- Initialize(vf1, Orthodont)
getGroups(vf1)
```

---

## getGroupsFormula *Extract Grouping Formula*

---

### Description

The conditioning expression associated with formula(object) (i.e. the expression after the | operator) is returned either as a named list of one-sided formulas, or a single one-sided formula, depending on the value of asList. The components of the returned list are ordered from outermost to innermost level and are named after the grouping factor expression.

### Usage

```
getGroupsFormula(object, asList, sep)
```

### Arguments

| | |
|---|---|
| object | any object from which a formula can be extracted. |
| asList | an optional logical value. If TRUE the returned value with be a list of formulas; else, if FALSE the returned value will be a one-sided formula. Defaults to FALSE. |
| sep | character, the separator to use between group levels when multiple levels are collapsed. The default is '/'. |

### Value

a one-sided formula, or a list of one-sided formulas, with the grouping structure associated with `formula(object)`. If no conditioning expression is present in `formula(object)` a `NULL` value is returned.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`getGroupsFormula.gls`, `getGroupsFormula.lmList`, `getGroupsFormula.lme`, `getGroupsFormula.reStruct`, `getGroups`

### Examples

```
getGroupsFormula(y ~ x | g1/g2)
```

---

## getResponse *Extract Response Variable from an Object*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `data.frame`, `gls`, `lme`, and `lmList`.

### Usage

```
getResponse(object, form)
```

### Arguments

| | |
|---|---|
| `object` | any object |
| `form` | an optional two-sided formula. Defaults to `formula(object)`. |

### Value

will depend on the method function used; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`getResponseFormula`

### Examples

```
getResponse(Orthodont)
```

## getResponseFormula *Extract Formula Specifying Response Variable*

### Description

The left hand side of `formula{object}` is returned as a one-sided formula.

### Usage

```
getResponseFormula(object)
```

### Arguments

| | |
|---|---|
| `object` | any object from which a formula can be extracted. |

### Value

a one-sided formula with the response variable associated with `formula{object}`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`getResponse`

### Examples

```
getResponseFormula(y ~ x | g)
```

## getVarCov *Extract variance-covariance matrix*

### Description

Extract the variance-covariance matrix from a fitted model, such as a mixed-effects model.

### Usage

```
getVarCov(obj, ...)
## S3 method for class 'lme'
getVarCov(obj, individuals,
    type = c("random.effects", "conditional", "marginal"), ...)
## S3 method for class 'gls'
getVarCov(obj, individual = 1, ...)
```

### Arguments

| | |
|---|---|
| obj | A fitted model. Methods are available for models fit by lme and by gls |
| individuals | For models fit by lme a vector of levels of the grouping factor can be specified for the conditional or marginal variance-covariance matrices. |
| individual | For models fit by gls the only type of variance-covariance matrix provided is the marginal variance-covariance of the responses by group. The optional argument individual specifies the group of responses. |
| type | For models fit by lme the type argument specifies the type of variance-covariance matrix, either "random.effects" for the random-effects variance-covariance (the default), or "conditional" for the conditional. variance-covariance of the responses or "marginal" for the the marginal variance-covariance of the responses. |
| ... | Optional arguments for some methods, as described above |

### Value

A variance-covariance matrix or a list of variance-covariance matrices.

### Author(s)

Mary Lindstrom <lindstro@biostat.wisc.edu>

### See Also

lme, gls

### Examples

```
fm1 <- lme(distance ~ age, data = Orthodont, subset = Sex == "Female")
getVarCov(fm1)
getVarCov(fm1, individual = "F01", type = "marginal")
getVarCov(fm1, type = "conditional")
fm2 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
getVarCov(fm2)
```

---

## gls — *Fit Linear Model Using Generalized Least Squares*

---

### Description

This function fits a linear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

### Usage

```
gls(model, data, correlation, weights, subset, method, na.action,
    control, verbose)
## S3 method for class 'gls'
update(object, model., ..., evaluate = TRUE)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "gls", representing a generalized least squares fitted linear model. |
| model | a two-sided linear formula object describing the model, with the response on the left of a ~ operator and the terms, separated by + operators, on the right. |
| model. | Changes to the model – see update.formula for details. |
| data | an optional data frame containing the variables named in model, correlation, weights, and subset. By default the variables are taken from the environment from which gls is called. |
| correlation | an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. If a grouping variable is to be used, it must be specified in the form argument to the corStruct constructor. Defaults to NULL, corresponding to uncorrelated errors. |
| weights | an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic errors. |
| subset | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| method | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML". |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes gls to print an error message and terminate if there are any incomplete observations. |
| control | a list of control values for the estimation algorithm to replace the default values returned by the function glsControl. Defaults to an empty list. |
| verbose | an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE. |
| ... | some methods for this generic require additional arguments. None are used in this method. |
| evaluate | If TRUE evaluate the new call else return the call. |

## Value

an object of class "gls" representing the linear model fit. Generic functions such as print, plot, and summary have methods to show the results of the fit. See glsObject for the components of the fit. The functions resid, coef and fitted, can be used to extract some of its components.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

## Examples

```
# AR(1) errors within each Mare
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
# variance increases as a power of the absolute fitted values
fm2 <- update(fm1, weights = varPower())
```

---

`glsControl` *Control Values for gls Fit*

---

## Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `gls` function.

## Usage

```
glsControl(maxIter, msMaxIter, tolerance, msTol, msVerbose,
           singular.ok, returnObject = FALSE, apVar, .relStep,
           opt = c("nlminb", "optim"), optimMethod,
           minAbsParApVar, natural, sigma = NULL)
```

## Arguments

| | |
|---|---|
| maxIter | maximum number of iterations for the gls optimization algorithm. Default is 50. |
| msMaxIter | maximum number of iterations for the optimization step inside the gls optimization. Default is 50. |
| tolerance | tolerance for the convergence criterion in the gls algorithm. Default is 1e-6. |
| msTol | tolerance for the convergence criterion of the first outer iteration when optim is used. Default is 1e-7. |
| msVerbose | a logical value passed as the trace argument to ms (see documentation on that function). Default is FALSE. |
| singular.ok | a logical value indicating whether non-estimable coefficients (resulting from linear dependencies among the columns of the regression matrix) should be allowed. Default is FALSE. |
| returnObject | a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE. |
| apVar | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE. |
| .relStep | relative step for numerical derivatives calculations. Default is .Machine$double.eps^(1/3). |
| opt | the optimizer to be used, either "nlminb" (the current default) or "optim" (the previous default). |
| optimMethod | character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B". |
| minAbsParApVar | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05. |
| natural | logical. Should the natural parameterization be used for the approximate variance calculations? Default is TRUE. |
| sigma | optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated. |

## Value

a list with components for each of the possible arguments.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

## See Also

gls

## Examples

```
# decrease the maximum number iterations in the optimization call and
# request that information on the evolution of the ms iterations be printed
glsControl(msMaxIter = 20, msVerbose = TRUE)
```

glsObject *Fitted gls Object*

## Description

An object returned by the gls function, inheriting from class "gls" and representing a generalized least squares fitted linear model. Objects of this class have methods for the generic functions anova, coef, fitted, formula, getGroups, getResponse, intervals, logLik, plot, predict, print, residuals, summary, and update.

## Value

The following components must be included in a legitimate "gls" object.

| | |
|---|---|
| apVar | an approximate covariance matrix for the variance-covariance coefficients. If apVar = FALSE in the list of control values used in the call to gls, this component is equal to NULL. |
| call | a list containing an image of the gls call that produced the object. |
| coefficients | a vector with the estimated linear model coefficients. |
| contrasts | a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list. |
| dims | a list with basic dimensions used in the model fit, including the components N - the number of observations in the data and p - the number of coefficients in the linear model. |
| fitted | a vector with the fitted values.. |
| glsStruct | an object inheriting from class glsStruct, representing a list of linear model components, such as corStruct and varFunc objects. |
| groups | a vector with the correlation structure grouping factor, if any is present. |
| logLik | the log-likelihood at convergence. |
| method | the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood. |
| numIter | the number of iterations used in the iterative algorithm. |
| residuals | a vector with the residuals. |
| sigma | the estimated residual standard error. |
| varBeta | an approximate covariance matrix of the coefficients estimates. |

## glsStruct — *Generalized Least Squares Structure*

### Description

A generalized least squares structure is a list of model components representing different sets of parameters in the linear model. A `glsStruct` may contain `corStruct` and `varFunc` objects. `NULL` arguments are not included in the `glsStruct` list.

### Usage

```
glsStruct(corStruct, varStruct)
```

### Arguments

| | |
|---|---|
| `corStruct` | an optional `corStruct` object, representing a correlation structure. Default is `NULL`. |
| `varStruct` | an optional `varFunc` object, representing a variance function structure. Default is `NULL`. |

### Value

a list of model variance-covariance components determining the parameters to be estimated for the associated linear model.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`corClasses`, `gls`, `residuals.glsStruct`, `varFunc`

### Examples

```
gls1 <- glsStruct(corAR1(), varPower())
```

## Glucose — *Glucose levels over time*

### Description

The `Glucose` data frame has 378 rows and 4 columns.

### Format

This data frame contains the following columns:

**Subject** an ordered factor with levels `6 < 2 < 3 < 5 < 1 < 4`

**Time** a numeric vector

**conc** a numeric vector of glucose levels

**Meal** an ordered factor with levels `2am < 6am < 10am < 2pm < 6pm < 10pm`

### Source

Hand, D. and Crowder, M. (1996), *Practical Longitudinal Data Analysis*, Chapman and Hall, London.

---

## Glucose2 — *Glucose Levels Following Alcohol Ingestion*

---

### Description

The `Glucose2` data frame has 196 rows and 4 columns.

### Format

This data frame contains the following columns:

**Subject** a factor with levels `1` to `7` identifying the subject whose glucose level is measured.

**Date** a factor with levels `1 2` indicating the occasion in which the experiment was conducted.

**Time** a numeric vector giving the time since alcohol ingestion (in min/10).

**glucose** a numeric vector giving the blood glucose level (in mg/dl).

### Details

Hand and Crowder (Table A.14, pp. 180-181, 1996) describe data on the blood glucose levels measured at 14 time points over 5 hours for 7 volunteers who took alcohol at time 0. The same experiment was repeated on a second date with the same subjects but with a dietary additive used for all subjects.

## gnls — *Fit Nonlinear Model Using Generalized Least Squares*

---

### Description

This function fits a nonlinear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

### Usage

```
gnls(model, data, params, start, correlation, weights, subset,
     na.action, naPattern, control, verbose)
```

## Arguments

| | |
|---|---|
| model | a two-sided formula object describing the model, with the response on the left of a ~ operator and a nonlinear expression involving parameters and covariates on the right. If data is given, all names used in the formula should be defined as parameters or variables in the data frame. |
| data | an optional data frame containing the variables named in model, correlation, weights, subset, and naPattern. By default the variables are taken from the environment from which gnls is called. |
| params | an optional two-sided linear formula of the form p1+...+pn~x1+...+xm, or list of two-sided formulas of the form p1~x1+...+xm, with possibly different models for each parameter. The p1,...,pn represent parameters included on the right hand side of model and x1+...+xm define a linear model for the parameters (when the left hand side of the formula contains several parameters, they are all assumed to follow the same linear model described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s). By default, the parameters are obtained from the names of start. |
| start | an optional named list, or numeric vector, with the initial values for the parameters in model. It can be omitted when a selfStarting function is used in model, in which case the starting estimates will be obtained from a single call to the nls function. |
| correlation | an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. If a grouping variable is to be used, it must be specified in the form argument to the corStruct constructor. Defaults to NULL, corresponding to uncorrelated errors. |
| weights | an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic errors. |
| subset | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes gnls to print an error message and terminate if there are any incomplete observations. |
| naPattern | an expression or formula object, specifying which returned values are to be regarded as missing. |
| control | a list of control values for the estimation algorithm to replace the default values returned by the function gnlsControl. Defaults to an empty list. |
| verbose | an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

## Value

an object of class gnls, also inheriting from class gls, representing the nonlinear model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See gnlsObject for the components of the fit. The functions resid, coef, and fitted can be used to extract some of its components.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

            weights = varPower())
summary(fm1)
```

---

gnlsControl *Control Values for gnls Fit*

---

## Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the gnls function.

## Usage

```
gnlsControl(maxIter = 50, nlsMaxIter = 7, msMaxIter = 50, minScale = 0.001,
            tolerance = 1e-6, nlsTol = 0.001, msTol = 1e-7,
            returnObject = FALSE, msVerbose = FALSE,
            apVar = TRUE, .relStep =,
            opt = c("nlminb", "optim"), optimMethod = "BFGS",
            minAbsParApVar = 0.05, sigma = NULL)
```

## Arguments

| | |
|---|---|
| `maxIter` | maximum number of iterations for the `gnls` optimization algorithm. Default is 50. |
| `nlsMaxIter` | maximum number of iterations for the `nls` optimization step *inside* the `gnls` optimization. Default is 7. |
| `msMaxIter` | maximum number of iterations for the `ms` optimization step inside the `gnls` optimization. Default is 50. |
| `minScale` | minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the `nls` step. Default 0.001. |
| `tolerance` | tolerance for the convergence criterion in the `gnls` algorithm. Default is 1e-6. |
| `nlsTol` | tolerance for the convergence criterion in `nls` step. Default is 1e-3. |
| `msTol` | tolerance for the convergence criterion of the first outer iteration when `optim` is used. Default is 1e-7. |
| `returnObject` | a logical value indicating whether the fitted object should be returned with a `warning` (instead of an error via `stop()`) when the maximum number of iterations is reached without convergence of the algorithm. |
| `msVerbose` | a logical value passed as the `trace` argument to the optimizer chosen by `opt`; see documentation on that. Default is `FALSE`. |
| `apVar` | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is `TRUE`. |
| `.relStep` | relative step for numerical derivatives calculations. Default is `.Machine$double.eps^(1/3)` (about 6e-6). |
| `opt` | the optimizer to be used, either `"nlminb"` (the current default) or `"optim"` (the previous default). |
| `optimMethod` | character - the optimization method to be used with the `optim` optimizer. The default is `"BFGS"`. An alternative is `"L-BFGS-B"`. |
| `minAbsParApVar` | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is `0.05`. |
| `sigma` | optionally a positive number to fix the residual error at. If `NULL`, as by default, or `0`, sigma is estimated. |

## Value

a list with components for each of the possible arguments.

gnlsObject *Fitted gnls Object*

---

## Description

An object returned by the gnls function, inheriting from class gnls and also from class gls, and representing a generalized nonlinear least squares fitted model. Objects of this class have methods for the generic functions anova, coef, fitted, formula, getGroups, getResponse, intervals, logLik, plot, predict, print, residuals, summary, and update.

## Value

The following components must be included in a legitimate gnls object.

| | |
|---|---|
| apVar | an approximate covariance matrix for the variance-covariance coefficients. If apVar = FALSE in the control values used in the call to gnls, this component is equal to NULL. |
| call | a list containing an image of the gnls call that produced the object. |
| coefficients | a vector with the estimated nonlinear model coefficients. |
| contrasts | a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list. |
| dims | a list with basic dimensions used in the model fit, including the components N - the number of observations used in the fit and p - the number of coefficients in the nonlinear model. |
| fitted | a vector with the fitted values. |
| modelStruct | an object inheriting from class gnlsStruct, representing a list of model components, such as corStruct and varFunc objects. |
| groups | a vector with the correlation structure grouping factor, if any is present. |
| logLik | the log-likelihood at convergence. |
| numIter | the number of iterations used in the iterative algorithm. |
| plist | |
| pmap | |
| residuals | a vector with the residuals. |
| sigma | the estimated residual standard error. |
| varBeta | an approximate covariance matrix of the coefficients estimates. |

gnlsStruct *Generalized Nonlinear Least Squares Structure*

---

### Description

A generalized nonlinear least squares structure is a list of model components representing different sets of parameters in the nonlinear model. A gnlsStruct may contain corStruct and varFunc objects. NULL arguments are not included in the gnlsStruct list.

### Usage

```
gnlsStruct(corStruct, varStruct)
```

### Arguments

| | |
|---|---|
| corStruct | an optional corStruct object, representing a correlation structure. Default is NULL. |
| varStruct | an optional varFunc object, representing a variance function structure. Default is NULL. |

### Value

a list of model variance-covariance components determining the parameters to be estimated for the associated nonlinear model.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

gnls, corClasses, residuals.gnlsStruct varFunc

### Examples

```
gnls1 <- gnlsStruct(corAR1(), varPower())
```

groupedData *Construct a groupedData Object*

## Description

An object of the groupedData class is constructed from the formula and data by attaching the formula as an attribute of the data, along with any of outer, inner, labels, and units that are given. If order.groups is TRUE the grouping factor is converted to an ordered factor with the ordering determined by FUN. Depending on the number of grouping levels and the type of primary covariate, the returned object will be of one of three classes: nfnGroupedData - numeric covariate, single level of nesting; nffGroupedData - factor covariate, single level of nesting; and nmGroupedData - multiple levels of nesting. Several modeling and plotting functions can use the formula stored with a groupedData object to construct default plots and models.

## Usage

```
groupedData(formula, data, order.groups, FUN, outer, inner,
 labels, units)
## S3 method for class 'groupedData'
update(object, formula, data, order.groups, FUN,
outer, inner, labels, units, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class groupedData. |
| formula | a formula of the form resp ~ cov \| group where resp is the response, cov is the primary covariate, and group is the grouping factor. The expression 1 can be used for the primary covariate when there is no other suitable candidate. Multiple nested grouping factors can be listed separated by the / symbol as in fact1/fact2. In an expression like this the fact2 factor is nested within the fact1 factor. |
| data | a data frame in which the expressions in formula can be evaluated. The resulting groupedData object will consist of the same data values in the same order but with additional attributes. |
| order.groups | an optional logical value, or list of logical values, indicating if the grouping factors should be converted to ordered factors according to the function FUN applied to the response from each group. If multiple levels of grouping are present, this argument can be either a single logical value (which will be repeated for all grouping levels) or a list of logical values. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). Ordering within a level of grouping is done within the levels of the grouping factors which are outer to it. Changing the grouping factor to an ordered factor does not affect the ordering of the rows in the data frame but it does affect the order of the panels in a trellis display of the data or models fitted to the data. Defaults to TRUE. |
| FUN | an optional summary function that will be applied to the values of the response for each level of the grouping factor, when order.groups = TRUE, to determine the ordering. Defaults to the max function. |

`outer` an optional one-sided formula, or list of one-sided formulas, indicating covariates that are outer to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. When plotting a groupedData object, the argument `outer = TRUE` causes the panels to be determined by the `outer` formula. The points within the panels are associated by level of the grouping factor. Defaults to `NULL`, meaning that no outer covariates are present.

`inner` an optional one-sided formula, or list of one-sided formulas, indicating covariates that are inner to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An inner covariate can change within the sets of rows defined by the grouping factor. An inner formula can be used to associate points in a plot of a groupedData object. Defaults to `NULL`, meaning that no inner covariates are present.

`labels` an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named `x` and that for the response is named `y`. Either label can be omitted.

`units` an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named `x` and that for the response is named `y`. Either units string can be omitted.

`...` some methods for this generic require additional arguments. None are used in this method.

## Value

an object of one of the classes `nfnGroupedData`, `nffGroupedData`, or `nmGroupedData`, and also inheriting from classes `groupedData` and `data.frame`.

## Examples

```
Orth.new <-  # create a new copy of the groupedData object
  groupedData( distance ~ age | Subject,
               data = as.data.frame( Orthodont ),
               FUN = mean,
               outer = ~ Sex,
               labels = list( x = "Age",
                 y = "Distance from pituitary to pterygomaxillary fissure" ),
               units = list( x = "(yr)", y = "(mm)") )
## Not run:
plot( Orth.new )         # trellis plot by Subject

## End(Not run)
formula( Orth.new )      # extractor for the formula
gsummary( Orth.new )     # apply summary by Subject
fm1 <- lme( Orth.new )   # fixed and groups formulae extracted from object
Orthodont2 <- update(Orthodont, FUN = mean)
```

---

`gsummary` *Summarize by Groups*

---

## Description

Provide a summary of the variables in a data frame by groups of rows. This is most useful with a `groupedData` object to examine the variables by group.

## Usage

```
gsummary(object, FUN, omitGroupingFactor, form, level,
   groups, invariantsOnly, ...)
```

## Arguments

`object` an object to be summarized - usually a `groupedData` object or a `data.frame`.

`FUN` an optional summary function or a list of summary functions to be applied to each variable in the frame. The function or functions are applied only to variables in `object` that vary within the groups defined by `groups`. Invariant variables are always summarized by group using the unique value that they assume within that group. If `FUN` is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If `FUN` is a list of functions, the names in the list should designate classes of variables in the frame such as `ordered`, `factor`, or `numeric`. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are `mean` for numeric factors, and `Mode` for both `factor` and `ordered`. The `Mode` function, defined internally in `gsummary`, returns the modal or most popular value of the variable. It is different from the `mode` function that returns the S-language mode of the variable.

`omitGroupingFactor` an optional logical value. When `TRUE` the grouping factor itself will be omitted from the group-wise summary but the levels of the grouping factor will continue to be used as the row names for the data frame that is produced by the summary. Defaults to `FALSE`.

| | |
|---|---|
| `form` | an optional one-sided formula that defines the groups. When this formula is given, the right-hand side is evaluated in `object`, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to `formula(object)`. |
| `level` | an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping. |
| `groups` | an optional factor that will be used to split the rows into groups. Defaults to `getGroups(object, form, level)`. |
| `invariantsOnly` | an optional logical value. When `TRUE` only those covariates that are invariant within each group will be summarized. The summary value for the group is always the unique value taken on by that covariate within the group. The columns in the summary are of the same class as the corresponding columns in `object`. By definition, the grouping factor itself must be an invariant. When combined with `omitGroupingFactor = TRUE`, this option can be used to discover is there are invariant covariates in the data frame. Defaults to `FALSE`. |
| `...` | optional additional arguments to the summary functions that are invoked on the variables by group. Often it is helpful to specify `na.rm = TRUE`. |

## Value

A `data.frame` with one row for each level of the grouping factor. The number of columns is at most the number of columns in `object`.

## Author(s)

## Examples

```
gsummary(Orthodont)  # default summary by Subject
## gsummary with invariantsOnly = TRUE and omitGroupingFactor = TRUE
## determines whether there are covariates like Sex that are invariant
## within the repeated observations on the same Subject.
gsummary(Orthodont, inv = TRUE, omit = TRUE)
```

## Gun — *Methods for firing naval guns*

### Description

The Gun data frame has 36 rows and 4 columns.

### Format

This data frame contains the following columns:

**rounds** a numeric vector

**Method** a factor with levels M1 M2

**Team** an ordered factor with levels T1S < T3S < T2S < T1A < T2A < T3A < T1H < T3H < T2H

**Physique** an ordered factor with levels Slight < Average < Heavy

### Details

Hicks (p.180, 1993) reports data from an experiment on methods for firing naval guns. Gunners of three different physiques (slight, average, and heavy) tested two firing methods. Both methods were tested twice by each of nine teams of three gunners with identical physique. The response was the number of rounds fired per minute.

### Source

Hicks, C. R. (1993), *Fundamental Concepts in the Design of Experiments (4th ed)*, Harcourt Brace, New York.

## IGF — *Radioimmunoassay of IGF-I Protein*

### Description

The IGF data frame has 237 rows and 3 columns.

### Format

This data frame contains the following columns:

**Lot** an ordered factor giving the radioactive tracer lot.

**age** a numeric vector giving the age (in days) of the radioactive tracer.

**conc** a numeric vector giving the estimated concentration of IGF-I protein (ng/ml)

### Details

Davidian and Giltinan (1995) describe data obtained during quality control radioimmunoassays for ten different lots of radioactive tracer used to calibrate the Insulin-like Growth Factor (IGF-I) protein concentration measurements.

## Initialize — *Initialize Object*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, `lmeStruct`, `reStruct`, and `varFunc`.

### Usage

```
Initialize(object, data, ...)
```

### Arguments

| | |
|---|---|
| `object` | any object requiring initialization, e.g. "plug-in" structures such as `corStruct` and `varFunc` objects. |
| `data` | a data frame to be used in the initialization procedure. |
| `...` | some methods for this generic function require additional arguments. |

### Value

an initialized object with the same class as `object`. Changes introduced by the initialization procedure will depend on the method function used; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

### See Also

`Initialize.corStruct`, `Initialize.lmeStruct`, `Initialize.glsStruct`, `Initialize.varFunc`, `isInitialized`

### Examples

```
## see the method function documentation
```

## Initialize.corStruct *Initialize corStruct Object*

### Description

This method initializes `object` by evaluating its associated covariate(s) and grouping factor, if any is present, in `data`, calculating various dimensions and constants used by optimization algorithms involving `corStruct` objects (see the appropriate `Dim` method documentation), and assigning initial values for the coefficients in `object`, if none were present.

### Usage

```
## S3 method for class 'corStruct'
Initialize(object, data, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`corStruct`" representing a correlation structure. |
| `data` | a data frame in which to evaluate the variables defined in `formula(object)`. |
| `...` | this argument is included to make this method compatible with the generic. |

### Value

an initialized object with the same class as `object` representing a correlation structure.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

### See Also

`Dim.corStruct`

### Examples

```
cs1 <- corAR1(form = ~ 1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
```

## Initialize.glsStruct *Initialize a glsStruct Object*

### Description

The individual linear model components of the `glsStruct` list are initialized.

### Usage

```
## S3 method for class 'glsStruct'
Initialize(object, data, control, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`glsStruct`", representing a list of linear model components, such as `corStruct` and `varFunc` objects. |
| `data` | a data frame in which to evaluate the variables defined in `formula(object)`. |
| `control` | an optional list with control parameters for the initialization and optimization algorithms used in `gls`. Defaults to `list(singular.ok = FALSE)`, implying that linear dependencies are not allowed in the model. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

a `glsStruct` object similar to `object`, but with initialized model components.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`gls`, `Initialize.corStruct`, `Initialize.varFunc`, `Initialize`

## Initialize.lmeStruct *Initialize an lmeStruct Object*

### Description

The individual linear mixed-effects model components of the `lmeStruct` list are initialized.

### Usage

```
## S3 method for class 'lmeStruct'
Initialize(object, data, groups, conLin, control, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"lmeStruct"`, representing a list of linear mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects. |
| `data` | a data frame in which to evaluate the variables defined in `formula(object)`. |
| `groups` | a data frame with the grouping factors corresponding to the lme model associated with `object` as columns, sorted from innermost to outermost grouping level. |
| `conLin` | an optional condensed linear model object, consisting of a list with components `"Xy"`, corresponding to a regression matrix (`X`) combined with a response vector (`y`), and `"logLik"`, corresponding to the log-likelihood of the underlying lme model. Defaults to `attr(object, "conLin")`. |
| `control` | an optional list with control parameters for the initialization and optimization algorithms used in `lme`. Defaults to `list(niterEM=20, gradHess=TRUE)`, implying that 20 EM iterations are to be used in the derivation of initial estimates for the coefficients of the `reStruct` component of `object` and, if possible, numerical gradient vectors and Hessian matrices for the log-likelihood function are to be used in the optimization algorithm. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

an `lmeStruct` object similar to `object`, but with initialized model components.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lme`, `Initialize.reStruct`, `Initialize.corStruct`, `Initialize.varFunc`, `Initialize`

---

## `Initialize.reStruct` *Initialize reStruct Object*

---

### Description

Initial estimates for the parameters in the `pdMat` objects forming `object`, which have not yet been initialized, are obtained using the methodology described in Bates and Pinheiro (1998). These estimates may be refined using a series of EM iterations, as described in Bates and Pinheiro (1998). The number of EM iterations to be used is defined in `control`.

### Usage

```
## S3 method for class 'reStruct'
Initialize(object, data, conLin, control, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects. |
| data | a data frame in which to evaluate the variables defined in formula(object). |
| conLin | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. |
| control | an optional list with a single component niterEM controlling the number of iterations for the EM algorithm used to refine initial parameter estimates. It is given as a list for compatibility with other Initialize methods. Defaults to list(niterEM = 20). |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

an reStruct object similar to object, but with all pdMat components initialized.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

reStruct, pdMat, Initialize

---

## Initialize.varFunc *Initialize varFunc Object*

---

### Description

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data; determining if the covariate(s) need to be updated when the values of the coefficients associated with object change; initializing the log-likelihood and the weights associated with object; and assigning initial values for the coefficients in object, if none were present. The covariate(s) will only be initialized if no update is needed when coef(object) changes.

### Usage

```
## S3 method for class 'varFunc'
Initialize(object, data, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "varFunc", representing a variance function structure. |
| data | a data frame in which to evaluate the variables named in formula(object). |
| ... | this argument is included to make this method compatible with the generic. |

### Value

an initialized object with the same class as `object` representing a variance function structure.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`Initialize`

### Examples

```
vf1 <- varPower( form = ~ age | Sex )
vf1 <- Initialize( vf1, Orthodont )
```

---

## intervals *Confidence Intervals on Coefficients*

---

### Description

Confidence intervals on the parameters associated with the model represented by `object` are obtained. This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

### Usage

```
intervals(object, level, ...)
```

### Arguments

| | |
|---|---|
| `object` | a fitted model object from which parameter estimates can be extracted. |
| `level` | an optional numeric value for the interval confidence level. Defaults to 0.95. |
| `...` | some methods for the generic may require additional arguments. |

### Value

will depend on the method function used; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

### See Also

`intervals.lme`, `intervals.lmList`, `intervals.gls`

### Examples

```
## see the method documentation
```

`intervals.gls` *Confidence Intervals on gls Parameters*

## Description

Approximate confidence intervals for the parameters in the linear model represented by `object` are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale.

## Usage

```
## S3 method for class 'gls'
intervals(object, level, which, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`gls`", representing a generalized least squares fitted linear model. |
| `level` | an optional numeric value for the interval confidence level. Defaults to 0.95. |
| `which` | an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "`all`" for all parameters, "`var-cov`" for the variance-covariance parameters only, and "`coef`" for the linear model coefficients only. Defaults to "`all`". |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

a list with components given by data frames with rows corresponding to parameters and columns `lower`, `est.`, and `upper` representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

| | |
|---|---|
| `coef` | linear model coefficients, only present when `which` is not equal to "`var-cov`". |
| `corStruct` | correlation parameters, only present when `which` is not equal to "`coef`" and a correlation structure is used in `object`. |
| `varFunc` | variance function parameters, only present when `which` is not equal to "`coef`" and a variance function structure is used in `object`. |
| `sigma` | residual standard error. |

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

## See Also

gls, intervals, print.intervals.gls

## Examples

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
intervals(fm1)
```

---

intervals.lme *Confidence Intervals on lme Parameters*

---

## Description

Approximate confidence intervals for the parameters in the linear mixed-effects model represented by `object` are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale. The `pdNatural` parametrization is used for general positive-definite matrices.

## Usage

```
## S3 method for class 'lme'
intervals(object, level = 0.95,
          which = c("all", "var-cov", "fixed"), ...)
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class "lme", representing a fitted linear mixed-effects model. |
| `level` | an optional numeric value with the confidence level for the intervals. Defaults to 0.95. |
| `which` | an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "fixed" for the fixed effects only. Defaults to "all". |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

a list with components given by data frames with rows corresponding to parameters and columns `lower`, `est.`, and `upper` representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

| | |
|---|---|
| `fixed` | fixed effects, only present when `which` is not equal to "var-cov". |
| `reStruct` | random effects variance-covariance parameters, only present when `which` is not equal to "fixed". |

| | |
|---|---|
| corStruct | within-group correlation parameters, only present when which is not equal to "fixed" and a correlation structure is used in object. |
| varFunc | within-group variance function parameters, only present when which is not equal to "fixed" and a variance function structure is used in object. |
| sigma | within-group standard deviation. |

## Author(s)

intervals(fm1)
```

---

# intervals.lmList *Confidence Intervals on lmList Coefficients*

---

## Description

Confidence intervals on the linear model coefficients are obtained for each lm component of object and organized into a three dimensional array. The first dimension corresponding to the names of the object components. The second dimension is given by lower, est., and upper corresponding, respectively, to the lower confidence limit, estimated coefficient, and upper confidence limit. The third dimension is given by the coefficients names.

## Usage

```
## S3 method for class 'lmList'
intervals(object, level = 0.95, pool = attr(object, "pool"), ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "lmList", representing a list of lm objects with a common model. |
| level | an optional numeric value with the confidence level for the intervals. Defaults to 0.95. |
| pool | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object, "pool"). |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

a three dimensional array with the confidence intervals and estimates for the coefficients of each `lm` component of `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

fm1 <- lmList(distance ~ age | Subject, Orthodont)
intervals(fm1)
```

---

## isBalanced *Check a Design for Balance*

---

### Description

Check the design of the experiment or study for balance.

### Usage

```
isBalanced(object, countOnly, level)
```

### Arguments

| | |
|---|---|
| `object` | A `groupedData` object containing a data frame and a formula that describes the roles of variables in the data frame. The object will have one or more nested grouping factors and a primary covariate. |
| `countOnly` | A logical value indicating if the check for balance should only consider the number of observations at each level of the grouping factor(s). Defaults to `FALSE`. |
| `level` | an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level. |

### Details

A design is balanced with respect to the grouping factor(s) if there are the same number of observations at each distinct value of the grouping factor or each combination of distinct levels of the nested grouping factors. If `countOnly` is `FALSE` the design is also checked for balance with respect to the primary covariate, which is often the time of the observation. A design is balanced with respect to the grouping factor and the covariate if the number of observations at each distinct level (or combination of levels for nested factors) is constant and the times at which the observations are taken (in general, the values of the primary covariates) also are constant.

### Value

TRUE or FALSE according to whether the data are balanced or not

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

table, groupedData

### Examples

```
isBalanced(Orthodont)                    # should return TRUE
isBalanced(Orthodont, countOnly = TRUE)  # should return TRUE
isBalanced(Pixel)                        # should return FALSE
isBalanced(Pixel, level = 1)             # should return FALSE
```

---

## isInitialized *Check if Object is Initialized*

---

### Description

Checks if object has been initialized (generally through a call to Initialize), by searching for components and attributes which are modified during initialization.

### Usage

```
isInitialized(object)
```

### Arguments

| | |
|---|---|
| object | any object requiring initialization. |

### Value

a logical value indicating whether object has been initialized.

### Author(s)

José Pinheiro and Douglas Bates

### See Also

Initialize

### Examples

```
pd1 <- pdDiag(~age)
isInitialized(pd1)
```

LDEsysMat *Generate system matrix for LDEs*

## Description

Generate the system matrix for the linear differential equations determined by a compartment model.

## Usage

```
LDEsysMat(pars, incidence)
```

## Arguments

| | |
|---|---|
| pars | a numeric vector of parameter values. |
| incidence | an integer matrix with columns named `From`, `To`, and `Par`. Values in the `Par` column must be in the range 1 to `length(pars)`. Values in the `From` column must be between 1 and the number of compartments. Values in the `To` column must be between 0 and the number of compartments. |

## Details

A compartment model describes material transfer between `k` in a system of `k` compartments to a linear system of differential equations. Given a description of the system and a vector of parameter values this function returns the system matrix.

This function is intended for use in a general system for solving compartment models, as described in Bates and Watts (1988).

## Value

A `k` by `k` numeric matrix.

## Author(s)

Douglas Bates <bates@stat.wisc.edu>

## References

Bates, D. M. and Watts, D. G. (1988), *Nonlinear Regression Analysis and Its Applications*, Wiley, New York.

## Examples

```
# incidence matrix for a two compartment open system
incidence <-
  matrix(c(1,1,2,2,2,1,3,2,0), ncol = 3, byrow = TRUE,
   dimnames = list(NULL, c("Par", "From", "To")))
incidence
LDEsysMat(c(1.2, 0.3, 0.4), incidence)
```

lme *Linear Mixed-Effects Models*

## Description

This generic function fits a linear mixed-effects model in the formulation described in Laird and Ware (1982) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

The methods `lme.lmList` and `lme.groupedData` are documented separately.

## Usage

```
lme(fixed, data, random, correlation, weights, subset, method,
    na.action, control, contrasts = NULL, keep.data = TRUE)

## S3 method for class 'lme'
update(object, fixed., ..., evaluate = TRUE)
```

## Arguments

`object` an object inheriting from class `lme`, representing a fitted linear mixed-effects model.

`fixed` a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a `~` operator and the terms, separated by `+` operators, on the right, an "`lmList`" object, or a "`groupedData`" object.

There is limited support for formulae such as `resp ~ 1` and `resp ~ 0`, and less prior to version '`3.1-112`'.

`fixed.` Changes to the fixed-effects formula – see `update.formula` for details.

`data` an optional data frame containing the variables named in `fixed`, `random`, `correlation`, `weights`, and `subset`. By default the variables are taken from the environment from which `lme` is called.

`random` optionally, any of the following: (i) a one-sided formula of the form `~ x1 + ... + xn | g1/.../gm`, with `x1 + ... + xn` specifying the model for the random effects and `g1/.../gm` the grouping structure (`m` may be equal to 1, in which case no `/` is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form `~ x1 + ... + xn | g`, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form `~ x1 + ... + xn`, or a `pdMat` object with a formula (i.e. a non-`NULL` value for `formula(object)`), or a list of such formulas or `pdMat` objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class "`groupedData`"; (iv) a named list of formulas or `pdMat` objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (v) an `reStruct` object. See the documentation on `pdClasses` for a description of the available `pdMat` classes. Defaults to a formula consisting of the right hand side of `fixed`.

| | |
|---|---|
| correlation | an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations. |
| weights | an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors. |
| subset | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| method | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML". |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lme to print an error message and terminate if there are any incomplete observations. |
| control | a list of control values for the estimation algorithm to replace the default values returned by the function lmeControl. Defaults to an empty list. |
| contrasts | an optional list. See the contrasts.arg of model.matrix.default. |
| keep.data | logical: should the data argument (if supplied and a data frame) be saved as part of the model object? |
| ... | some methods for this generic require additional arguments. None are used in this method. |
| evaluate | If TRUE evaluate the new call else return the call. |

## Value

An object of class "lme" representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

## Note

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

## Author(s)

## Examples

```
fm1 <- lme(distance ~ age, data = Orthodont) # random is ~ age
fm2 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
summary(fm1)
summary(fm2)
```

---

# lme.groupedData *LME fit from groupedData Object*

---

## Description

The response variable and primary covariate in `formula(fixed)` are used to construct the fixed effects model formula. This formula and the `groupedData` object are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.

## Usage

```
## S3 method for class 'groupedData'
lme(fixed, data, random, correlation, weights,
    subset, method, na.action, control, contrasts, keep.data = TRUE)
```

### Arguments

| | |
|---|---|
| fixed | a data frame inheriting from class "groupedData". |
| data | this argument is included for consistency with the generic function. It is ignored in this method function. |
| random | optionally, any of the following: (i) a one-sided formula of the form ~x1+...+xn \| g1/.../gm, with x1+...+xn specifying the model for the random effects and g1/.../gm the grouping structure (m may be equal to 1, in which case no / is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form ~x1+...+xn \| g, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form ~x1+...+xn, or a pdMat object with a formula (i.e. a non-NULL value for formula(object)), or a list of such formulas or pdMat objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class groupedData; (iv) a named list of formulas or pdMat objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (v) an reStruct object. See the documentation on pdClasses for a description of the available pdMat classes. Defaults to a formula consisting of the right hand side of fixed. |
| correlation | an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations. |
| weights | an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors. |
| subset | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| method | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML". |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lme to print an error message and terminate if there are any incomplete observations. |
| control | a list of control values for the estimation algorithm to replace the default values returned by the function lmeControl. Defaults to an empty list. |
| contrasts | an optional list. See the contrasts.arg of model.matrix.default. |
| keep.data | logical: should the data argument (if supplied and a data frame) be saved as part of the model object? |

### Value

an object of class lme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the

components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

summary(fm1)
```

lme.lmList *LME fit from lmList Object*

## Description

If the random effects names defined in random are a subset of the lmList object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in random). formula(fixed) and the data argument in the calling sequence used to obtain fixed are passed as the fixed and data arguments to lme.formula, together with any other additional arguments in the function call. See the documentation on lme.formula for a description of that function.

## Usage

```
## S3 method for class 'lmList'
lme(fixed, data, random, correlation, weights, subset, method,
    na.action, control, contrasts, keep.data)
```

## Arguments

| | |
|---|---|
| fixed | an object inheriting from class "lmList.", representing a list of lm fits with a common model. |
| data | this argument is included for consistency with the generic function. It is ignored in this method function. |
| random | an optional one-sided linear formula with no conditioning expression, or a pdMat object with a formula attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of formula(fixed). |
| correlation | an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations. |
| weights | an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors. |
| subset | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| method | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML". |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lme to print an error message and terminate if there are any incomplete observations. |
| control | a list of control values for the estimation algorithm to replace the default values returned by the function lmeControl. Defaults to an empty list. |

| | |
|---|---|
| contrasts | an optional list. See the contrasts.arg of model.matrix.default. |
| keep.data | logical: should the data argument (if supplied and a data frame) be saved as part of the model object? |

## Value

an object of class lme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. lmeControl *Specifying Control Values for lme Fit*

## Description

The values supplied in the `lmeControl()` call replace the defaults, and a `list` with all settings (i.e., values for all possible arguments) is returned. The returned list is used as the `control` argument to the `lme` function.

## Usage

```
lmeControl(maxIter = 50, msMaxIter = 50, tolerance = 1e-6, niterEM = 25,
           msMaxEval = 200,
   msTol = 1e-7, msVerbose = FALSE,
           returnObject = FALSE, gradHess = TRUE, apVar = TRUE,
   .relStep = .Machine$double.eps^(1/3), minAbsParApVar = 0.05,
           opt = c("nlminb", "optim"),
   optimMethod = "BFGS", natural = TRUE,
   sigma = NULL, ...)
```

## Arguments

| | |
|---|---|
| `maxIter` | maximum number of iterations for the `lme` optimization algorithm. Default is `50`. |
| `msMaxIter` | maximum number of iterations for the optimization step inside the `lme` optimization. Default is `50`. |
| `tolerance` | tolerance for the convergence criterion in the `lme` algorithm. Default is `1e-6`. |
| `niterEM` | number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is `25`. |
| `msMaxEval` | maximum number of evaluations of the objective function permitted for nlminb. Default is `200`. |
| `msTol` | tolerance for the convergence criterion on the first iteration when `optim` is used. Default is `1e-7`. |
| `msVerbose` | a logical value passed as the `trace` argument to `nlminb` or `optim`. Default is `FALSE`. |
| `returnObject` | a logical value indicating whether the fitted object should be returned with a `warning` (instead of an error via `stop()`) when the maximum number of iterations is reached without convergence of the algorithm. Default is `FALSE`. |
| `gradHess` | a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the internal optimization. This option is only available when the correlation structure (`corStruct`) and the variance function structure (`varFunc`) have no "varying" parameters and the `pdMat` classes used in the random effects structure are `pdSymm` (general positive-definite), `pdDiag` (diagonal), `pdIdent` (multiple of the identity), or `pdCompSymm` (compound symmetry). Default is `TRUE`. |
| `apVar` | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is `TRUE`. |

| | |
|---|---|
| .relStep | relative step for numerical derivatives calculations. Default is .Machine$double.eps^(1/3). |
| opt | the optimizer to be used, either "nlminb" (the default) or "optim". |
| optimMethod | character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B". |
| minAbsParApVar | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05. |
| natural | a logical value indicating whether the pdNatural parametrization should be used for general positive-definite matrices (pdSymm) in reStruct, when the approximate covariance matrix of the estimators is calculated. Default is TRUE. |
| sigma | optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated. |
| ... | further named control arguments to be passed, depending on opt, to nlminb (those from abs.tol down) or optim (those except trace and maxit; reltol is used only from the second iteration). |

## Value

a list with components for each of the possible arguments.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

## See Also

lme, nlminb, optim

## Examples

```
# decrease the maximum number iterations in the ms call and
# request that information on the evolution of the ms iterations be printed
str(lCtr <- lmeControl(msMaxIter = 20, msVerbose = TRUE))
## This should always work:
do.call(lmeControl, lCtr)
```

---

lmeObject *Fitted lme Object*

---

## Description

An object returned by the lme function, inheriting from class lme and representing a fitted linear mixed-effects model. Objects of this class have methods for the generic functions anova, coef, fitted, fixed.effects, formula, getGroups, getResponse, intervals, logLik, pairs, plot, predict, print, random.effects, residuals, sigma, summary, update, and vcov.

## Value

The following components must be included in a legitimate `lme` object.

- `apVar` — an approximate covariance matrix for the variance-covariance coefficients. If `apVar = FALSE` in the control values used in the call to `lme`, this component is `NULL`.
- `call` — a list containing an image of the `lme` call that produced the object.
- `coefficients` — a list with two components, `fixed` and `random`, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the `random` list, the columns refer to the random effects and the rows to the groups.
- `contrasts` — a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the lme model, this component will be an empty list.
- `dims` — a list with basic dimensions used in the lme fit, including the components `N` - the number of observations in the data, `Q` - the number of grouping levels, `qvec` - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), `ngrps` - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and `ncol` - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).
- `fitted` — a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.
- `fixDF` — a list with components `X` and `terms` specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.
- `groups` — a data frame with the grouping factors as columns. The grouping level increases from left to right.
- `logLik` — the (restricted) log-likelihood at convergence.
- `method` — the estimation method: either `"ML"` for maximum likelihood, or `"REML"` for restricted maximum likelihood.
- `modelStruct` — an object inheriting from class `lmeStruct`, representing a list of mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.
- `numIter` — the number of iterations used in the iterative algorithm.
- `residuals` — a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.
- `sigma` — the estimated within-group error standard deviation.
- `varFix` — an approximate covariance matrix of the fixed effects estimates.

---

lmeStruct *Linear Mixed-Effects Structure*

---

## Description

A linear mixed-effects structure is a list of model components representing different sets of parameters in the linear mixed-effects model. An lmeStruct list must contain at least a reStruct object, but may also contain corStruct and varFunc objects. NULL arguments are not included in the lmeStruct list.

## Usage

```
lmeStruct(reStruct, corStruct, varStruct)
```

## Arguments

| | |
|---|---|
| reStruct | a reStruct representing a random effects structure. |
| corStruct | an optional corStruct object, representing a correlation structure. Default is NULL. |
| varStruct | an optional varFunc object, representing a variance function structure. Default is NULL. |

## Value

a list of model components determining the parameters to be estimated for the associated linear mixed-effects model.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

lmList *List of lm Objects with a Common Model*

## Description

Data is partitioned according to the levels of the grouping factor g and individual lm fits are obtained for each data partition, using the model defined in object.

## Usage

```
lmList(object, data, level, subset, na.action = na.fail,
       pool = TRUE, warn.lm = TRUE)
## S3 method for class 'lmList'
update(object, formula., ..., evaluate = TRUE)
## S3 method for class 'lmList'
print(x, pool, ...)
```

## Arguments

| | |
|---|---|
| object | For lmList, either a linear formula object of the form y ~ x1+...+xn \| g or a groupedData object. In the formula object, y represents the response, x1,...,xn the covariates, and g the grouping factor specifying the partitioning of the data according to which different lm fits should be performed. The grouping factor g may be omitted from the formula, in which case the grouping structure will be obtained from data, which must inherit from class groupedData. The method function lmList.groupedData is documented separately. For the method update.lmList, object is an object inheriting from class lmList. |
| formula | (used in update.lmList only) a two-sided linear formula with the common model for the individuals lm fits. |
| formula. | Changes to the formula – see update.formula for details. |
| data | a data frame in which to interpret the variables named in object. |
| level | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present. |
| subset | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lmList to print an error message and terminate if there are any incomplete observations. |
| pool | an optional logical value indicating whether a pooled estimate of the residual standard error should be used in calculations of standard deviations or standard errors for summaries. |
| warn.lm | logical indicating if lm() errors (all of which are caught by tryCatch) should be signalled as a "summarizing" warning. |
| x | an object inheriting from class lmList to be printed. |
| ... | some methods for this generic require additional arguments. None are used in this method. |
| evaluate | If TRUE evaluate the new call else return the call. |

### Value

a list of lm objects with as many components as the number of groups defined by the grouping factor. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an lmList object.

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

### See Also

lm, lme.lmList, plot.lmList, pooledSD, predict.lmList, residuals.lmList, summary.lmList

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
summary(fm1)
```

---

## lmList.groupedData *lmList Fit from a groupedData Object*

---

### Description

The response variable and primary covariate in formula(object) are used to construct the linear model formula. This formula and the groupedData object are passed as the object and data arguments to lmList.formula, together with any other additional arguments in the function call. See the documentation on lmList.formula for a description of that function.

### Usage

```
## S3 method for class 'groupedData'
lmList(object, data, level, subset, na.action = na.fail,
       pool = TRUE, warn.lm = TRUE)
```

### Arguments

| | |
|---|---|
| object | a data frame inheriting from class "groupedData". |
| data | this argument is included for consistency with the generic function. It is ignored in this method function. |
| level | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present. |
| subset | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lmList to print an error message and terminate if there are any incomplete observations. |
| pool, warn.lm | optional logicals, see lmList. |

### Value

a list of `lm` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `lmList` object.

### See Also

`groupedData`, `lm`, `lme.lmList`, `lmList`, `lmList.formula`

### Examples

```
fm1 <- lmList(Orthodont)
summary(fm1)
```

---

## logDet — *Extract the Logarithm of the Determinant*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, several `pdMat` classes, and `reStruct`.

### Usage

```
logDet(object, ...)
```

### Arguments

| | |
|---|---|
| `object` | any object from which a matrix, or list of matrices, can be extracted |
| `...` | some methods for this generic function require additional arguments. |

### Value

will depend on the method function used; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`logLik`, `logDet.corStruct`, `logDet.pdMat`, `logDet.reStruct`

### Examples

```
## see the method function documentation
```

## logDet.corStruct — *Extract corStruct Log-Determinant*

### Description

This method function extracts the logarithm of the determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

### Usage

```
## S3 method for class 'corStruct'
logDet(object, covariate, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`corStruct`", representing a correlation structure. |
| `covariate` | an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to `getCovariate(object)`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

the log-determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`logLik.corStruct`, `corMatrix.corStruct`, `logDet`

### Examples

```
cs1 <- corAR1(0.3)
logDet(cs1, covariate = 1:4)
```

## logDet.pdMat — *Extract Log-Determinant from a pdMat Object*

### Description

This method function extracts the logarithm of the determinant of a square-root factor of the positive-definite matrix represented by `object`.

### Usage

```
## S3 method for class 'pdMat'
logDet(object, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`pdMat`", representing a positive definite matrix. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

the log-determinant of a square-root factor of the positive-definite matrix represented by `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`pdMat`, `logDet`

### Examples

```
pd1 <- pdSymm(diag(1:3))
logDet(pd1)
```

## logDet.reStruct — *Extract reStruct Log-Determinants*

### Description

Calculates, for each of the `pdMat` components of `object`, the logarithm of the determinant of a square-root factor.

### Usage

```
## S3 method for class 'reStruct'
logDet(object, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

a vector with the log-determinants of square-root factors of the pdMat components of object.

### Author(s)

José Pinheiro

### See Also

reStruct, pdMat, logDet

### Examples

```
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
  B = pdDiag(2 * diag(4), form = ~Educ)))
logDet(rs1)
```

---

## logLik.corStruct *Extract corStruct Log-Likelihood*

---

### Description

This method function extracts the component of a Gaussian log-likelihood associated with the correlation structure, which is equal to the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the matrix (or matrices) represented by object.

### Usage

```
## S3 method for class 'corStruct'
logLik(object, data, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "corStruct", representing a correlation structure. |
| data | this argument is included to make this method function compatible with other logLik methods and will be ignored. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the correlation matrix (or matrices) represented by object.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

logDet.corStruct, logLik.lme,

### Examples

```
cs1 <- corAR1(0.2)
cs1 <- Initialize(cs1, data = Orthodont)
logLik(cs1)
```

---

## logLik.glsStruct *Log-Likelihood of a glsStruct Object*

---

### Description

Pars is used to update the coefficients of the model components of object and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the settings attribute of object.

### Usage

```
## S3 method for class 'glsStruct'
logLik(object, Pars, conLin, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and "varFunc" objects. |
| Pars | the parameter values at which the (restricted) log-likelihood is to be evaluated. |
| conLin | an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying linear model. Defaults to attr(object, "conLin"). |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

the (restricted) log-likelihood for the linear model described by object, evaluated at Pars.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

gls, glsStruct, logLik.lme

## logLik.gnls — *Log-Likelihood of a gnls Object*

### Description

Returns the log-likelihood value of the nonlinear model represented by `object` evaluated at the estimated coefficients.

### Usage

```
## S3 method for class 'gnls'
logLik(object, REML, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`gnls`", representing a generalized nonlinear least squares fitted model. |
| `REML` | an logical value for consistency with `logLik,gls`, but only `FALSE` is accepted.. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

the log-likelihood of the linear model represented by `object` evaluated at the estimated coefficients.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`gnls`, `logLik.lme`

### Examples

```
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
            weights = varPower())
logLik(fm1)
```

## logLik.gnlsStruct — *Log-Likelihood of a gnlsStruct Object*

### Description

`Pars` is used to update the coefficients of the model components of `object` and the individual log-likelihood contributions of each component are added together.

### Usage

```
## S3 method for class 'gnlsStruct'
logLik(object, Pars, conLin, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class gnlsStruct, representing a list of model components, such as corStruct and varFunc objects, and attributes specifying the underlying nonlinear model and the response variable. |
| Pars | the parameter values at which the log-likelihood is to be evaluated. |
| conLin | an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nonlinear model. Defaults to attr(object, "conLin"). |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

the log-likelihood for the linear model described by object, evaluated at Pars.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

gnls, gnlsStruct, logLik.gnls

---

## logLik.lme *Log-Likelihood of an lme Object*

---

### Description

If REML=FALSE, returns the log-likelihood value of the linear mixed-effects model represented by object evaluated at the estimated coefficients; else, the restricted log-likelihood evaluated at the estimated coefficients is returned.

### Usage

```
## S3 method for class 'lme'
logLik(object, REML, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "lme", representing a fitted linear mixed-effects model. |
| REML | an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to the method of estimation used, that is TRUE if and only object was fitted with method = "REML" (the default for these fitting functions) . |
| ... | some methods for this generic require additional arguments. None are used in this method. |

## Value

the (restricted) log-likelihood of the model represented by `object` evaluated at the estimated coefficients.

## Author(s)

José Pinheiro and Douglas Bates

## Examples

```
fm1 <- lme(distance ~ Sex * age, Orthodont, random = ~ age, method = "ML")
logLik(fm1)
logLik(fm1, REML = TRUE)
```

---

`logLik.lmeStruct` *Log-Likelihood of an lmeStruct Object*

---

## Description

`Pars` is used to update the coefficients of the model components of `object` and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the `settings` attribute of `object`.

## Usage

```
## S3 method for class 'lmeStruct'
logLik(object, Pars, conLin, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"lmeStruct"`, representing a list of linear mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects. |
| `Pars` | the parameter values at which the (restricted) log-likelihood is to be evaluated. |
| `conLin` | an optional condensed linear model object, consisting of a list with components `"Xy"`, corresponding to a regression matrix (`X`) combined with a response vector (`y`), and `"logLik"`, corresponding to the log-likelihood of the underlying lme model. Defaults to `attr(object, "conLin")`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

the (restricted) log-likelihood for the linear mixed-effects model described by `object`, evaluated at `Pars`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lme`, `lmeStruct`, `logLik.lme`

---

## logLik.lmList — *Log-Likelihood of an lmList Object*

---

### Description

If `pool=FALSE`, the (restricted) log-likelihoods of the `lm` components of `object` are summed together. Else, the (restricted) log-likelihood of the `lm` fit with different coefficients for each level of the grouping factor associated with the partitioning of the `object` components is obtained.

### Usage

```
## S3 method for class 'lmList'
logLik(object, REML, pool, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"lmList"`, representing a list of `lm` objects with a common model. |
| `REML` | an optional logical value. If `TRUE` the restricted log-likelihood is returned, else, if `FALSE`, the log-likelihood is returned. Defaults to `FALSE`. |
| `pool` | an optional logical value indicating whether all `lm` components of `object` may be assumed to have the same error variance. Default is `attr(object, "pool")`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

either the sum of the (restricted) log-likelihoods of each `lm` component in `object`, or the (restricted) log-likelihood for the `lm` fit with separate coefficients for each component of `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lmList`, `logLik.lme`,

## Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
logLik(fm1)   # returns NA when it should not
```

---

`logLik.reStruct` *Calculate reStruct Log-Likelihood*

---

## Description

Calculates the log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)`. The `settings` attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods are described in Bates and Pinheiro (1998).

## Usage

```
## S3 method for class 'reStruct'
logLik(object, conLin, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"reStruct"`, representing a random effects structure and consisting of a list of `pdMat` objects. |
| `conLin` | a condensed linear model object, consisting of a list with components `"Xy"`, corresponding to a regression matrix (`X`) combined with a response vector (`y`), and `"logLik"`, corresponding to the log-likelihood of the underlying model. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

the log-likelihood, or restricted log-likelihood, of linear mixed-effects model represented by `object` and `conLin`, evaluated at `coef{object}`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

`reStruct`, `pdMat`, `logLik.lme`

`logLik.varFunc` *Extract varFunc logLik*

## Description

This method function extracts the component of a Gaussian log-likelihood associated with the variance function structure represented by `object`, which is equal to the sum of the logarithms of the corresponding weights.

## Usage

```
## S3 method for class 'varFunc'
logLik(object, data, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`varFunc`", representing a variance function structure. |
| `data` | this argument is included to make this method function compatible with other `logLik` methods and will be ignored. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

the sum of the logarithms of the weights corresponding to the variance function structure represented by `object`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

`logLik.lme`

## Examples

```
vf1 <- varPower(form = ~age)
vf1 <- Initialize(vf1, Orthodont)
coef(vf1) <- 0.1
logLik(vf1)
```

## Machines — *Productivity Scores for Machines and Workers*

### Description

The `Machines` data frame has 54 rows and 3 columns.

### Format

This data frame contains the following columns:

**Worker** an ordered factor giving the unique identifier for the worker.

**Machine** a factor with levels `A`, `B`, and `C` identifying the machine brand.

**score** a productivity score.

### Details

Data on an experiment to compare three brands of machines used in an industrial process are presented in Milliken and Johnson (p. 285, 1992). Six workers were chosen randomly among the employees of a factory to operate each machine three times. The response is an overall productivity score taking into account the number and quality of components produced.

## MathAchieve — *Mathematics achievement scores*

### Description

The `MathAchieve` data frame has 7185 rows and 6 columns.

### Format

This data frame contains the following columns:

**School** an ordered factor identifying the school that the student attends

**Minority** a factor with levels `No` `Yes` indicating if the student is a member of a minority racial group.

**Sex** a factor with levels `Male` `Female`

**SES** a numeric vector of socio-economic status.

**MathAch** a numeric vector of mathematics achievement scores.

**MEANSES** a numeric vector of the mean SES for the school.

## Details

Each row in this data frame contains the data for one student.

## Examples

```
summary(MathAchieve)
```

---

`MathAchSchool` *School demographic data for MathAchieve*

---

## Description

The `MathAchSchool` data frame has 160 rows and 7 columns.

## Format

This data frame contains the following columns:

**School** a factor giving the school on which the measurement is made.

**Size** a numeric vector giving the number of students in the school

**Sector** a factor with levels `Public` `Catholic`

**PRACAD** a numeric vector giving the percentage of students on the academic track

**DISCLIM** a numeric vector measuring the discrimination climate

**HIMINTY** a factor with levels `0` `1`

**MEANSES** a numeric vector giving the mean SES score.

## Details

These variables give the school-level demographic data to accompany the `MathAchieve` data.

---

`Matrix` *Assign Matrix Values*

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `pdMat`, `pdBlocked`, and `reStruct`.

## Usage

```
matrix(object) <- value
```

## Arguments

| | |
|---|---|
| `object` | any object to which `as.matrix` can be applied. |
| `value` | a matrix, or list of matrices, with the same dimensions as `as.matrix(object)` with the new values to be assigned to the matrix associated with `object`. |

### Value

will depend on the method function; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

as.matrix, also for examples, matrix<-.pdMat, matrix<-.reStruct.

---

## Matrix.pdMat — *Assign Matrix to a pdMat or pdBlocked Object*

---

### Description

The positive-definite matrix represented by object is replaced by value. If the original matrix had row and/or column names, the corresponding names for value can either be NULL, or a permutation of the original names.

### Usage

```
## S3 replacement method for class 'pdMat'
matrix(object) <- value
## S3 replacement method for class 'pdBlocked'
matrix(object) <- value
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "pdMat", representing a positive definite matrix. |
| value | a matrix with the new values to be assigned to the positive-definite matrix represented by object. Must have the same dimensions as as.matrix(object). |

### Value

a pdMat or pdBlocked object similar to object, but with its coefficients modified to produce the matrix in value.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

pdMat, "matrix<-"

### Examples

```
class(pd1 <- pdSymm(diag(3))) # "pdSymm" "pdMat"
matrix(pd1) <- diag(1:3)
pd1
```

## Matrix.reStruct *Assign reStruct Matrices*

### Description

The individual matrices in value are assigned to each pdMat component of object, in the order they are listed. The new matrices must have the same dimensions as the matrices they are meant to replace.

### Usage

```
## S3 replacement method for class 'reStruct'
matrix(object) <-  value
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects. |
| value | a matrix, or list of matrices, with the new values to be assigned to the matrices associated with the pdMat components of object. |

### Value

an reStruct object similar to object, but with the coefficients of the individual pdMat components modified to produce the matrices listed in value.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

reStruct, pdMat, "matrix<-"

### Examples

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
matrix(rs1) <- list(diag(2), 3)
```

## Meat *Tenderness of meat*

### Description

The Meat data frame has 30 rows and 4 columns.

### Format

This data frame contains the following columns:

**Storage** an ordered factor specifying the storage treatment - 1 (0 days), 2 (1 day), 3 (2 days), 4 (4 days), 5 (9 days), and 6 (18 days)

**score** a numeric vector giving the tenderness score of beef roast.

**Block** an ordered factor identifying the muscle from which the roast was extracted with levels `II` < `V` < `I` < `III` < `IV`

**Pair** an ordered factor giving the unique identifier for each pair of beef roasts with levels `II-1` < ... < `IV-1`

### Details

Cochran and Cox (section 11.51, 1957) describe data from an experiment conducted at Iowa State College (Paul, 1943) to compare the effects of length of cold storage on the tenderness of beef roasts. Six storage periods ranging from 0 to 18 days were used. Thirty roasts were scored by four judges on a scale from 0 to 10, with the score increasing with tenderness. The response was the sum of all four scores. Left and right roasts from the same animal were grouped into pairs, which were further grouped into five blocks, according to the muscle from which they were extracted. Different storage periods were applied to each roast within a pair according to a balanced incomplete block design.

---

## `Milk` *Protein content of cows' milk*

---

### Description

The `Milk` data frame has 1337 rows and 4 columns.

### Format

This data frame contains the following columns:

**protein** a numeric vector giving the protein content of the milk.

**Time** a numeric vector giving the time since calving (weeks).

**Cow** an ordered factor giving a unique identifier for each cow.

**Diet** a factor with levels `barley`, `barley+lupins`, and `lupins` identifying the diet for each cow.

### Details

Diggle, Liang, and Zeger (1994) describe data on the protein content of cows' milk in the weeks following calving. The cattle are grouped according to whether they are fed a diet with barley alone, with barley and lupins, or with lupins alone.

### Source

Diggle, Peter J., Liang, Kung-Yee and Zeger, Scott L. (1994), *Analysis of longitudinal data*, Oxford University Press, Oxford.

## model.matrix.reStruct *reStruct Model Matrix*

### Description

The model matrices for each element of `formula(object)`, calculated using `data`, are bound together column-wise. When multiple grouping levels are present (i.e. when `length(object) > 1`), the individual model matrices are combined from innermost (at the leftmost position) to outermost (at the rightmost position).

### Usage

```
## S3 method for class 'reStruct'
model.matrix(object, data, contrast, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`reStruct`", representing a random effects structure and consisting of a list of `pdMat` objects. |
| `data` | a data frame in which to evaluate the variables defined in `formula(object)`. |
| `contrast` | an optional named list specifying the contrasts to be used for representing the `factor` variables in `data`. The components names should match the names of the variables in `data` for which the contrasts are to be specified. The components of this list will be used as the `contrasts` attribute of the corresponding factor. If missing, the default contrast specification is used. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

a matrix obtained by binding together, column-wise, the model matrices for each element of `formula(object)`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`model.matrix`, `contrasts`, `reStruct`, `formula.reStruct`

### Examples

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
model.matrix(rs1, Pixel)
```

## Muscle — *Contraction of heart muscle sections*

### Description

The `Muscle` data frame has 60 rows and 3 columns.

### Format

This data frame contains the following columns:

**Strip** an ordered factor indicating the strip of muscle being measured.

**conc** a numeric vector giving the concentration of CaCl2

**length** a numeric vector giving the shortening of the heart muscle strip.

### Details

Baumann and Waldvogel (1963) describe data on the shortening of heart muscle strips dipped in a $CaCl_2$ solution. The muscle strips are taken from the left auricle of a rat's heart.

### Source

Baumann, F. and Waldvogel, F. (1963), La restitution pastsystolique de la contraction de l'oreillette gauche du rat. Effets de divers ions et de l'acetylcholine, *Helvetica Physiologica Acta*, **21**.

## Names — *Names Associated with an Object*

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `formula`, `modelStruct`, `pdBlocked`, `pdMat`, and `reStruct`.

### Usage

```
Names(object, ...)
Names(object, ...) <- value
```

### Arguments

| | |
|---|---|
| `object` | any object for which names can be extracted and/or assigned. |
| `...` | some methods for this generic function require additional arguments. |
| `value` | names to be assigned to `object`. |

### Value

will depend on the method function used; see the appropriate documentation.

### SIDE EFFECTS

On the left side of an assignment, sets the names associated with `object` to `value`, which must have an appropriate length.

### Note

If `names` were generic, there would be no need for this generic function.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`Names.formula`, `Names.pdMat`

### Examples

```
## see the method function documentation
```

---

## Names.formula — *Extract Names from a formula*

---

### Description

This method function returns the names of the terms corresponding to the right hand side of `object` (treated as a linear formula), obtained as the column names of the corresponding `model.matrix`.

### Usage

```
## S3 method for class 'formula'
Names(object, data, exclude, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`formula`". |
| `data` | an optional data frame containing the variables specified in `object`. By default the variables are taken from the environment from which `Names.formula` is called. |
| `exclude` | an optional character vector with names to be excluded from the returned value. Default is `c("pi",".")`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

a character vector with the column names of the `model.matrix` corresponding to the right hand side of `object` which are not listed in `excluded`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

model.matrix, terms, Names

## Examples

```
Names(distance ~ Sex * age, data = Orthodont)
```

---

Names.pdBlocked *Names of a pdBlocked Object*

---

## Description

This method function extracts the first element of the Dimnames attribute, which contains the column names, for each block diagonal element in the matrix represented by object.

## Usage

```
## S3 method for class 'pdBlocked'
Names(object, asList, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "pdBlocked" representing a positive-definite matrix with block diagonal structure |
| asList | a logical value. If TRUE a list with the names for each block diagonal element is returned. If FALSE a character vector with all column names is returned. Defaults to FALSE. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

## Value

if asList is FALSE, a character vector with column names of the matrix represented by object; otherwise, if asList is TRUE, a list with components given by the column names of the individual block diagonal elements in the matrix represented by object.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

Names, Names.pdMat

## Examples

```
pd1 <- pdBlocked(list(~Sex - 1, ~age - 1), data = Orthodont)
Names(pd1)
```

Names.pdMat *Names of a pdMat Object*

## Description

This method function returns the fist element of the Dimnames attribute of object, which contains the column names of the matrix represented by object.

## Usage

```
## S3 method for class 'pdMat'
Names(object, ...)
## S3 replacement method for class 'pdMat'
Names(object, ...) <- value
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "pdMat", representing a positive-definite matrix. |
| value | a character vector with the replacement values for the column and row names of the matrix represented by object. It must have length equal to the dimension of the matrix represented by object and, if names have been previously assigned to object, it must correspond to a permutation of the original names. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

## Value

if object has a Dimnames attribute then the first element of this attribute is returned; otherwise NULL.

## SIDE EFFECTS

On the left side of an assignment, sets the Dimnames attribute of object to list(value, value).

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

Names, Names.pdBlocked

## Examples

```
pd1 <- pdSymm(~age, data = Orthodont)
Names(pd1)
```

Names.reStruct *Names of an reStruct Object*

## Description

This method function extracts the column names of each of the positive-definite matrices represented the pdMat elements of object.

## Usage

```
## S3 method for class 'reStruct'
Names(object, ...)
## S3 replacement method for class 'reStruct'
Names(object, ...) <- value
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects. |
| value | a list of character vectors with the replacement values for the names of the individual pdMat objects that form object. It must have the same length as object. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

## Value

a list containing the column names of each of the positive-definite matrices represented by the pdMat elements of object.

## SIDE EFFECTS

On the left side of an assignment, sets the Names of the pdMat elements of object to the corresponding element of value.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

reStruct, pdMat, Names.pdMat

## Examples

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
Names(rs1)
```

## needUpdate *Check if Update is Needed*

### Description

This function is generic; method functions can be written to handle specific classes of objects. By default, it tries to extract a `needUpdate` attribute of `object`. If this is `NULL` or `FALSE` it returns `FALSE`; else it returns `TRUE`. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

### Usage

```
needUpdate(object)
```

### Arguments

| | |
|---|---|
| `object` | any object |

### Value

a logical value indicating whether `object` needs to be updated.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`needUpdate.modelStruct`

### Examples

```
vf1 <- varExp()
vf1 <- Initialize(vf1, data = Orthodont)
needUpdate(vf1)
```

## needUpdate.modelStruct *Check if a modelStruct Object Needs Updating*

### Description

This method function checks if any of the elements of `object` needs to be updated. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

### Usage

```
## S3 method for class 'modelStruct'
needUpdate(object)
```

### Arguments

`object` an object inheriting from class `"modelStruct"`, representing a list of model components, such as `corStruct` and `varFunc` objects.

### Value

a logical value indicating whether any element of `object` needs to be updated.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`needUpdate`

### Examples

```
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
   varStruct = varPower(form = ~age))
needUpdate(lms1)
```

---

## Nitrendipene *Assay of nitrendipene*

---

### Description

The `Nitrendipene` data frame has 89 rows and 4 columns.

### Format

This data frame contains the following columns:

**activity** a numeric vector

**NIF** a numeric vector

**Tissue** an ordered factor with levels 2 < 1 < 3 < 4

**log.NIF** a numeric vector

### Source

Bates, D. M. and Watts, D. G. (1988), *Nonlinear Regression Analysis and Its Applications*, Wiley, New York.

nlme *Nonlinear Mixed-Effects Models*

## Description

This generic function fits a nonlinear mixed-effects model in the formulation described in Lindstrom and Bates (1990) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

## Usage

```
nlme(model, data, fixed, random, groups, start, correlation, weights,
     subset, method, na.action, naPattern, control, verbose)
```

## Arguments

`model` a nonlinear model formula, with the response on the left of a ~ operator and an expression involving parameters and covariates on the right, or an `nlsList` object. If `data` is given, all names used in the formula should be defined as parameters or variables in the data frame. The method function `nlme.nlsList` is documented separately.

`data` an optional data frame containing the variables named in `model`, `fixed`, `random`, `correlation`, `weights`, `subset`, and `naPattern`. By default the variables are taken from the environment from which `nlme` is called.

`fixed` a two-sided linear formula of the form `f1+...+fn~x1+...+xm`, or a list of two-sided formulas of the form `f1~x1+...+xm`, with possibly different models for different parameters. The `f1,...,fn` are the names of parameters included on the right hand side of `model` and the `x1+...+xm` expressions define linear models for these parameters (when the left hand side of the formula contains several parameters, they all are assumed to follow the same linear model, described by the right hand side expression). A `1` on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s).

`random` optionally, any of the following: (i) a two-sided formula of the form `r1+...+rn~x1+...+xm | g1/.../gQ`, with `r1,...,rn` naming parameters included on the right hand side of `model`, `x1+...+xm` specifying the random-effects model for these parameters and `g1/.../gQ` the grouping structure (`Q` may be equal to 1, in which case no `/` is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a two-sided formula of the form `r1+...+rn~x1+..+xm`, a list of two-sided formulas of the form `r1~x1+...+xm`, with possibly different random-effects models for different parameters, a `pdMat` object with a two-sided formula, or list of two-sided formulas (i.e. a non-`NULL` value for `formula(random)`), or a list of pdMat objects with two-sided formulas, or lists of two-sided formulas. In this case, the grouping structure formula will be given in `groups`, or derived from the data used to fit the nonlinear mixed-effects model, which should inherit from class `groupedData`,; (iii) a named list of formulas, lists of formulas, or `pdMat` objects as in (ii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (iv) an `reStruct` object. See the documentation on `pdClasses` for a description of the available `pdMat` classes. Defaults to `fixed`, resulting in all fixed effects having also random effects.

groups — an optional one-sided formula of the form ~g1 (single level of nesting) or ~g1/.../gQ (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. g1,...,gQ must evaluate to factors in data. The order of nesting, when multiple levels are present, is taken from left to right (i.e. g1 is the first level, g2 the second, etc.).

start — an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component fixed, given by the vector. The fixed component is required, unless the model function inherits from class selfStart, in which case initial values will be derived from a call to nlsList. An optional random component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level.

correlation — an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations.

weights — an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors.

subset — an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method — a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".

na.action — a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlme to print an error message and terminate if there are any incomplete observations.

naPattern — an expression or formula object, specifying which returned values are to be regarded as missing.

control — a list of control values for the estimation algorithm to replace the default values returned by the function nlmeControl. Defaults to an empty list.

verbose — an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

## Value

an object of class nlme representing the nonlinear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See nlmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

## Note

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

The model formulation and computational methods are described in Lindstrom, M.J. and Bates, D.M. (1990). The variance-covariance parametrizations are described in Pinheiro, J.C. and Bates., D.M. (1996). The different correlation structures available for the `correlation` argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littel, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). The use of variance functions for linear and nonlinear mixed effects models is presented in detail in Davidian, M. and Giltinan, D.M. (1995).

## Examples

```
fm1 <- nlme(height ~ SSasymp(age, Asym, R0, lrc),
            data = Loblolly,
            fixed = Asym + R0 + lrc ~ 1,
            random = Asym ~ 1,
            start = c(Asym = 103, R0 = -8.5, lrc = -3.3))
summary(fm1)
fm2 <- update(fm1, random = pdDiag(Asym + lrc ~ 1))
summary(fm2)
```

nlme.nlsList *NLME fit from nlsList Object*

## Description

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain `fixed` are passed as the `fixed` and `data` arguments to `nlme.formula`, together with any other additional arguments in the function call. See the documentation on `nlme.formula` for a description of that function.

## Usage

```
## S3 method for class 'nlsList'
nlme(model, data, fixed, random, groups, start, correlation, weights,
     subset, method, na.action, naPattern, control, verbose)
```

## Arguments

| | |
|---|---|
| `model` | an object inheriting from class "`nlsList`", representing a list of `nls` fits with a common model. |
| `data` | this argument is included for consistency with the generic function. It is ignored in this method function. |
| `fixed` | this argument is included for consistency with the generic function. It is ignored in this method function. |
| `random` | an optional one-sided linear formula with no conditioning expression, or a `pdMat` object with a `formula` attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of `formula(fixed)`. |
| `groups` | an optional one-sided formula of the form `~g1` (single level of nesting) or `~g1/.../gQ` (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. `g1,...,gQ` must evaluate to factors in `data`. The order of nesting, when multiple levels are present, is taken from left to right (i.e. `g1` is the first level, `g2` the second, etc.). |
| `start` | an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component `fixed`, given by the vector. The `fixed` component is required, unless the model function inherits from class `selfStart`, in which case initial values will be derived from a call to `nlsList`. An optional `random` component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level. |
| `correlation` | an optional `corStruct` object describing the within-group correlation structure. See the documentation of `corClasses` for a description of the available `corStruct` classes. Defaults to `NULL`, corresponding to no within-group correlations. |

| | |
|---|---|
| weights | an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors. |
| subset | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| method | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML". |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlme to print an error message and terminate if there are any incomplete observations. |
| naPattern | an expression or formula object, specifying which returned values are to be regarded as missing. |
| control | a list of control values for the estimation algorithm to replace the default values returned by the function nlmeControl. Defaults to an empty list. |
| verbose | an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE. |

## Value

an object of class nlme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See nlmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

```

---

# nlmeControl *Control Values for nlme Fit*

---

## Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `nlme` function.

## Usage

```
nlmeControl(maxIter, pnlsMaxIter, msMaxIter, minScale,
            tolerance, niterEM, pnlsTol, msTol,
            returnObject, msVerbose, msWarnNoConv,
            gradHess, apVar, .relStep, minAbsParApVar = 0.05,
            opt = c("nlminb", "nlm"), natural = TRUE, sigma = NULL, ...)
```

## Arguments

| | |
|---|---|
| `maxIter` | maximum number of iterations for the `nlme` optimization algorithm. Default is 50. |
| `pnlsMaxIter` | maximum number of iterations for the `PNLS` optimization step inside the `nlme` optimization. Default is 7. |
| `msMaxIter` | maximum number of iterations for `nlminb` (`iter.max`) or the `nlm` (`iterlim`, from the 10-th step) optimization step inside the `nlme` optimization. Default is 50 (which may be too small for e.g. for overparametrized cases). |
| `minScale` | minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the `PNLS` step. Default `0.001`. |
| `tolerance` | tolerance for the convergence criterion in the `nlme` algorithm. Default is `1e-6`. |
| `niterEM` | number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25. |
| `pnlsTol` | tolerance for the convergence criterion in `PNLS` step. Default is `1e-3`. |

| | |
|---|---|
| msTol | tolerance for the convergence criterion in nlm, passed as the gradtol argument to the function (see documentation on nlm). Default is 1e-7. |
| returnObject | a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE. |
| msVerbose | a logical value passed as the trace to nlminb(.., control= list(trace = *, ..)) or as argument print.level to nlm(). Default is FALSE. |
| msWarnNoConv | logical indicating if a warning should be signalled whenever the minimization by (opt) in the LME step does not converge; defaults to TRUE. |
| gradHess | a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the nlm optimization. This option is only available when the correlation structure (corStruct) and the variance function structure (varFunc) have no "varying" parameters and the pdMat classes used in the random effects structure are pdSymm (general positive-definite), pdDiag (diagonal), pdIdent (multiple of the identity), or pdCompSymm (compound symmetry). Default is TRUE. |
| apVar | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE. |
| .relStep | relative step for numerical derivatives calculations. Default is .Machine$double.eps^(1/3). |
| minAbsParApVar | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05. |
| opt | the optimizer to be used, either "nlminb" (the default) or "nlm". |
| natural | a logical value indicating whether the pdNatural parametrization should be used for general positive-definite matrices (pdSymm) in reStruct, when the approximate covariance matrix of the estimators is calculated. Default is TRUE. |
| sigma | optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated. |
| ... | Further, named control arguments to be passed to nlminb (apart from trace and iter.max mentioned above), where used (eval.max and those from abs.tol down). |

## Value

a list with components for each of the possible arguments.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

## See Also

nlme, nlm, optim, nlmeStruct

## Examples

```
# decrease the maximum number iterations in the ms call and
# request that information on the evolution of the ms iterations be printed
nlmeControl(msMaxIter = 20, msVerbose = TRUE)
```

nlmeObject *Fitted nlme Object*

## Description

An object returned by the nlme function, inheriting from class "nlme", also inheriting from class "lme", and representing a fitted nonlinear mixed-effects model. Objects of this class have methods for the generic functions anova, coef, fitted, fixed.effects, formula, getGroups, getResponse, intervals, logLik, pairs, plot, predict, print, random.effects, residuals, summary, and update.

## Value

The following components must be included in a legitimate "nlme" object.

apVar — an approximate covariance matrix for the variance-covariance coefficients. If apVar = FALSE in the control values used in the call to nlme, this component is NULL.

call — a list containing an image of the nlme call that produced the object.

coefficients — a list with two components, fixed and random, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the random list, the columns refer to the random effects and the rows to the groups.

contrasts — a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the nlme model, this component will be an empty list.

dims — a list with basic dimensions used in the nlme fit, including the components N - the number of observations in the data, Q - the number of grouping levels, qvec - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), ngrps - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and ncol - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).

fitted — a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.

fixDF — a list with components X and terms specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.

groups — a data frame with the grouping factors as columns. The grouping level increases from left to right.

logLik — the (restricted) log-likelihood at convergence.

map — a list with components fmap, rmap, rmapRel, and bmap, specifying various mappings for the fixed and random effects, used to generate predictions from the fitted object.

| | |
|---|---|
| method | the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood. |
| modelStruct | an object inheriting from class nlmeStruct, representing a list of mixed-effects model components, such as reStruct, corStruct, and varFunc objects. |
| numIter | the number of iterations used in the iterative algorithm. |
| residuals | a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping. |
| sigma | the estimated within-group error standard deviation. |
| varFix | an approximate covariance matrix of the fixed effects estimates. |

nlmeStruct *Nonlinear Mixed-Effects Structure*

---

## Description

A nonlinear mixed-effects structure is a list of model components representing different sets of parameters in the nonlinear mixed-effects model. An nlmeStruct list must contain at least a reStruct object, but may also contain corStruct and varFunc objects. NULL arguments are not included in the nlmeStruct list.

## Usage

```
nlmeStruct(reStruct, corStruct, varStruct)
```

## Arguments

| | |
|---|---|
| reStruct | a reStruct representing a random effects structure. |
| corStruct | an optional corStruct object, representing a correlation structure. Default is NULL. |
| varStruct | an optional varFunc object, representing a variance function structure. Default is NULL. |

## Value

a list of model components determining the parameters to be estimated for the associated nonlinear mixed-effects model.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

corClasses, nlme, residuals.nlmeStruct, reStruct, varFunc

## Examples

```
nlms1 <- nlmeStruct(reStruct(~age), corAR1(), varPower())
```

---

nlsList *List of nls Objects with a Common Model*

---

## Description

Data is partitioned according to the levels of the grouping factor defined in model and individual nls fits are obtained for each data partition, using the model defined in model.

## Usage

```
nlsList(model, data, start, control, level, subset,
        na.action = na.fail, pool = TRUE, warn.nls = NA)
## S3 method for class 'nlsList'
update(object, model., ..., evaluate = TRUE)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class nlsList, representing a list of fitted nls objects. |
| model | either a nonlinear model formula, with the response on the left of a ~ operator and an expression involving parameters, covariates, and a grouping factor separated by the \| operator on the right, or a selfStart function. The method function nlsList.selfStart is documented separately. |
| model. | changes to the model – see update.formula for details. |
| data | a data frame in which to interpret the variables named in model. |
| start | an optional named list with initial values for the parameters to be estimated in model. It is passed as the start argument to each nls call and is required when the nonlinear function in model does not inherit from class selfStart. |
| control | a list of control values passed as the control argument to nls. Defaults to an empty list. |
| level | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present. |
| subset | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlsList to print an error message and terminate if there are any incomplete observations. |
| pool | an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for pool in calculations of standard deviations or standard errors for summaries. |

| | |
|---|---|
| warn.nls | logical indicating if nls() errors (all of which are caught by tryCatch) should be signalled as a "summarizing" warning. |
| ... | some methods for this generic require additional arguments. None are used in this method. |
| evaluate | If TRUE evaluate the new call else return the call. |

## Details

As nls(.) is called on each sub group, and convergence of these may be problematic, these calls happen with error catching.

Since **nlme** version 3.1-127 (2016-04), all the errors are caught (via tryCatch) and if present, a "summarizing" warning is stored as attribute of the resulting "nlsList" object and signalled unless suppressed by warn.nls = FALSE or currently also when warn.nls = NA (default) *and* getOption("show.error.messages") is false.

nlsList() originally had used try(*) (with its default silent=FALSE) and hence all errors were printed to the console *unless* the global option show.error.messages was set to true. This still works, but has been *deprecated*.

## Value

a list of nls objects with as many components as the number of groups defined by the grouping factor. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an nlsList object.

## References

## Examples

```
fm1 <- nlsList(uptake ~ SSasympOff(conc, Asym, lrc, c0),
   data = CO2, start = c(Asym = 30, lrc = -4.5, c0 = 52))
summary(fm1)
cfm1 <- confint(fm1) # via profiling each % FIXME: only *one* message instead of one *each*
stopifnot((i.ok <- which(sapply(cfm1, class) == "matrix"))
          %in% c(2:4,6:9, 12))
## where as (some of) the others gave errors during profile re-fitting :
str(cfm1[- i.ok])
```

---

nlsList.selfStart *nlsList Fit from a selfStart Function*

---

## Description

The response variable and primary covariate in formula(data) are used together with model to construct the nonlinear model formula. This is used in the nls calls and, because a selfStarting model function can calculate initial estimates for its parameters from the data, no starting estimates need to be provided.

## Usage

```
## S3 method for class 'selfStart'
nlsList(model, data, start, control, level, subset,
        na.action = na.fail, pool = TRUE, warn.nls = NA)
```

## Arguments

| | |
|---|---|
| model | a "selfStart" model function, which calculates initial estimates for the model parameters from data. |
| data | a data frame in which to interpret the variables in model. Because no grouping factor can be specified in model, data must inherit from class "groupedData". |
| start | an optional named list with initial values for the parameters to be estimated in model. It is passed as the start argument to each nls call and is required when the nonlinear function in model does not inherit from class selfStart. |
| control | a list of control values passed as the control argument to nls. Defaults to an empty list. |
| level | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present. |
| subset | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlsList to print an error message and terminate if there are any incomplete observations. |
| pool, warn.nls | optional logicals, see nlsList. |

## Value

a list of nls objects with as many components as the number of groups defined by the grouping factor. A NULL value is assigned to the components corresponding to clusters for which the nls algorithm failed to converge. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an nlsList object.

fm1 <- nlsList(SSasympOff, CO2)
summary(fm1)
```

## Oats — *Split-plot Experiment on Varieties of Oats*

### Description

The `Oats` data frame has 72 rows and 4 columns.

### Format

This data frame contains the following columns:

**Block** an ordered factor with levels `VI` < `V` < `III` < `IV` < `II` < `I`

**Variety** a factor with levels `Golden Rain` `Marvellous` `Victory`

**nitro** a numeric vector

**yield** a numeric vector

### Details

These data have been introduced by Yates (1935) as an example of a split-plot design. The treatment structure used in the experiment was a $3 \times 4$ full factorial, with three varieties of oats and four concentrations of nitrogen. The experimental units were arranged into six blocks, each with three whole-plots subdivided into four subplots. The varieties of oats were assigned randomly to the whole-plots and the concentrations of nitrogen to the subplots. All four concentrations of nitrogen were used on each whole-plot.

## Orthodont — *Growth curve data on an orthdontic measurement*

### Description

The `Orthodont` data frame has 108 rows and 4 columns of the change in an orthdontic measurement over time for several young subjects.

### Format

This data frame contains the following columns:

**distance** a numeric vector of distances from the pituitary to the pterygomaxillary fissure (mm). These distances are measured on x-ray images of the skull.

**age** a numeric vector of ages of the subject (yr).

**Subject** an ordered factor indicating the subject on which the measurement was made. The levels are labelled `M01` to `M16` for the males and `F01` to `F13` for the females. The ordering is by increasing average distance within sex.

**Sex** a factor with levels `Male` and `Female`

## Details

Investigators at the University of North Carolina Dental School followed the growth of 27 children (16 males, 11 females) from age 8 until age 14. Every two years they measured the distance between the pituitary and the pterygomaxillary fissure, two points that are easily identified on x-ray exposures of the side of the head.

plot(Orthodont)
```

---

`Ovary` *Counts of Ovarian Follicles*

---

## Description

The `Ovary` data frame has 308 rows and 3 columns.

## Format

This data frame contains the following columns:

**Mare** an ordered factor indicating the mare on which the measurement is made.

**Time** time in the estrus cycle. The data were recorded daily from 3 days before ovulation until 3 days after the next ovulation. The measurement times for each mare are scaled so that the ovulations for each mare occur at times 0 and 1.

**follicles** the number of ovarian follicles greater than 10 mm in diameter.

## Details

Pierson and Ginther (1987) report on a study of the number of large ovarian follicles detected in different mares at several times in their estrus cycles.

## Source

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York. (Appendix A.18)

## Oxboys — *Heights of Boys in Oxford*

### Description

The Oxboys data frame has 234 rows and 4 columns.

### Format

This data frame contains the following columns:

**Subject** an ordered factor giving a unique identifier for each boy in the experiment

**age** a numeric vector giving the standardized age (dimensionless)

**height** a numeric vector giving the height of the boy (cm)

**Occasion** an ordered factor - the result of converting age from a continuous variable to a count so these slightly unbalanced data can be analyzed as balanced.

### Details

These data are described in Goldstein (1987) as data on the height of a selection of boys from Oxford, England versus a standardized age.

### Source

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York. (Appendix A.19)

## Oxide — *Variability in Semiconductor Manufacturing*

### Description

The Oxide data frame has 72 rows and 5 columns.

### Format

This data frame contains the following columns:

**Source** a factor with levels 1 and 2

**Lot** a factor giving a unique identifier for each lot.

**Wafer** a factor giving a unique identifier for each wafer within a lot.

**Site** a factor with levels 1, 2, and 3

**Thickness** a numeric vector giving the thickness of the oxide layer.

## Details

These data are described in Littell et al. (1996, p. 155) as coming "from a passive data collection study in the semiconductor industry where the objective is to estimate the variance components to determine the assignable causes of the observed variability." The observed response is the thickness of the oxide layer on silicon wafers, measured at three different sites of each of three wafers selected from each of eight lots sampled from the population of lots.

---

`pairs.compareFits` *Pairs Plot of compareFits Object*

---

## Description

Scatter plots of the values being compared are generated for each pair of coefficients in `x`. Different symbols (colors) are used for each object being compared and values corresponding to the same group are joined by a line, to facilitate comparison of fits. If only two coefficients are present, the `trellis` function `xyplot` is used; otherwise the `trellis` function `splom` is used.

## Usage

```
## S3 method for class 'compareFits'
pairs(x, subset, key, ...)
```

## Arguments

| | |
|---|---|
| `x` | an object of class `compareFits`. |
| `subset` | an optional logical or integer vector specifying which rows of `x` should be used in the plots. If missing, all rows are used. |
| `key` | an optional logical value, or list. If `TRUE`, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If `FALSE`, no legend is included. If given as a list, `key` is passed down as an argument to the `trellis` function generating the plots (`splom` or `xyplot`). Defaults to `TRUE`. |
| `...` | optional arguments passed down to the `trellis` function generating the plots. |

## Value

Pairwise scatter plots of the values being compared, with different symbols (colors) used for each object under comparison.

## Author(s)

José Pinheiro and Douglas Bates

### See Also

compareFits, plot.compareFits, pairs.lme, pairs.lmList, xyplot, splom

### Examples

```
fm1 <- lmList(Orthodont)
fm2 <- lme(Orthodont)
pairs(compareFits(coef(fm1), coef(fm2)))
```

---

## pairs.lme *Pairs Plot of an lme Object*

---

### Description

Diagnostic plots for the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a `|` operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function `xyplot` is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function `splom` is used).

### Usage

```
## S3 method for class 'lme'
pairs(x, form, label, id, idLabels, grid, ...)
```

### Arguments

| | |
|---|---|
| `x` | an object inheriting from class "lme", representing a fitted linear mixed-effects model. |
| `form` | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain `x` can be referenced. In addition, `x` itself can be referenced in the formula using the symbol `"."`. Conditional expressions on the right of a `|` operator can be used to define separate panels in a Trellis display. The expression on the right hand side of `form`, and to the left of the `|` operator, must evaluate to a data frame with at least two columns. Default is `~ coef(.)` , corresponding to a pairs plot of the coefficients evaluated at the innermost level of nesting. |
| `label` | an optional character vector of labels for the variables in the pairs plot. |
| `id` | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the $1 - value$ percentile of the appropriate chi-square distribution are identified in the plot using `idLabels`. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified. |

| | |
|---|---|
| idLabels | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor. |
| grid | an optional logical value indicating whether a grid should be added to plot. Default is FALSE. |
| ... | optional arguments passed to the Trellis plot function. |

## Value

a diagnostic Trellis plot.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
# scatter plot of coefficients by gender, identifying unusual subjects
pairs(fm1, ~coef(., augFrame = TRUE) | Sex, id = 0.1, adj = -0.5)
# scatter plot of estimated random effects
## Not run:
pairs(fm1, ~ranef(.))

## End(Not run)
```

---

# pairs.lmList *Pairs Plot of an lmList Object*

---

## Description

Diagnostic plots for the linear model fits corresponding to the x components are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a | operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function xyplot is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function splom is used).

## Usage

```
## S3 method for class 'lmList'
pairs(x, form, label, id, idLabels, grid, ...)
```

### Arguments

| | |
|---|---|
| `x` | an object inheriting from class "`lmList`", representing a list of `lm` objects with a common model. |
| `form` | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain `x` can be referenced. In addition, `x` itself can be referenced in the formula using the symbol "`.`". Conditional expressions on the right of a `\|` operator can be used to define separate panels in a Trellis display. The expression on the right hand side of `form`, and to the left of the `\|` operator, must evaluate to a data frame with at least two columns. Default is `~ coef(.)` , corresponding to a pairs plot of the coefficients of `x`. |
| `label` | an optional character vector of labels for the variables in the pairs plot. |
| `id` | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the $1 - value$ percentile of the appropriate chi-square distribution are identified in the plot using `idLabels`. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified. |
| `idLabels` | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to `id`. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor. |
| `grid` | an optional logical value indicating whether a grid should be added to plot. Default is `FALSE`. |
| `...` | optional arguments passed to the Trellis plot function. |

### Value

a diagnostic Trellis plot.

## End(Not run)
```

PBG *Effect of Phenylbiguanide on Blood Pressure*

## Description

The PBG data frame has 60 rows and 5 columns.

## Format

This data frame contains the following columns:

**deltaBP** a numeric vector

**dose** a numeric vector

**Run** an ordered factor with levels T5 < T4 < T3 < T2 < T1 < P5 < P3 < P2 < P4 < P1

**Treatment** a factor with levels MDL 72222 Placebo

**Rabbit** an ordered factor with levels 5 < 3 < 2 < 4 < 1

## Details

Data on an experiment to examine the effect of a antagonist MDL 72222 on the change in blood pressure experienced with increasing dosage of phenylbiguanide are described in Ludbrook (1994) and analyzed in Venables and Ripley (2002, section 10.3). Each of five rabbits was exposed to increasing doses of phenylbiguanide after having either a placebo or the HD5-antagonist MDL 72222 administered.

pdBlocked *Positive-Definite Block Diagonal Matrix*

## Description

This function is a constructor for the pdBlocked class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual pdMat object. When value is numeric(0), a list of uninitialized pdMat objects, a list of one-sided formulas, or a list of vectors of character strings, object is returned as an uninitialized pdBlocked object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is a list of initialized pdMat objects, object will be constructed from the list obtained by applying as.matrix to each of the pdMat elements of value. Finally, if value is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

## Usage

```
pdBlocked(value, form, nam, data, pdClass)
```

## Arguments

| | |
|---|---|
| value | an optional list with elements to be used as the value argument to other pdMat constructors. These include: pdMat objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to numeric(0), corresponding to an uninitialized object. |
| form | an optional list of one-sided linear formulas specifying the row/column names for the block-diagonal elements of the matrix represented by object. Because factors may be present in form, the formulas needs to be evaluated on a data.frame to resolve the names they define. This argument is ignored when value is a list of one-sided formulas. Defaults to NULL. |
| nam | an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by object. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when value is a list of vector of character strings. Defaults to NULL. |
| data | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on any factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| pdClass | an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm". |

## Value

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. p. 162.

## See Also

## Examples

```
pd1 <- pdBlocked(list(diag(1:2), diag(c(0.1, 0.2, 0.3))),
                 nam = list(c("A","B"), c("a1", "a2", "a3")))
pd1
```

pdClasses *Positive-Definite Matrix Classes*

## Description

Standard classes of positive-definite matrices (pdMat) structures available in the nlme package.

## Value

Available standard classes:

| | |
|---|---|
| pdSymm | general positive-definite matrix, with no additional structure |
| pdLogChol | general positive-definite matrix, with no additional structure, using a log-Cholesky parameterization |
| pdDiag | diagonal |
| pdIdent | multiple of an identity |
| pdCompSymm | compound symmetry structure (constant diagonal and constant off-diagonal elements) |
| pdBlocked | block-diagonal matrix, with diagonal blocks of any "atomic" pdMat class |
| pdNatural | general positive-definite matrix in natural parametrization (i.e. parametrized in terms of standard deviations and correlations). The underlying coefficients are not unrestricted, so this class should NOT be used for optimization. |

## Note

Users may define their own pdMat classes by specifying a constructor function and, at a minimum, methods for the functions pdConstruct, pdMatrix and coef. For examples of these functions, see the methods for classes pdSymm and pdDiag.

pdCompSymm *Positive-Definite Matrix with Compound Symmetry Structure*

## Description

This function is a constructor for the pdCompSymm class, representing a positive-definite matrix with compound symmetry structure (constant diagonal and constant off-diagonal elements). The underlying matrix is represented by 2 unrestricted parameters. When value is numeric(0), an unitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdCompSymm object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector of length 2, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

## Usage

```
pdCompSymm(value, form, nam, data)
```

## Arguments

| | |
|---|---|
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector of length 2. Defaults to numeric(0), corresponding to an uninitialized object. |
| form | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL. |
| nam | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL. |
| data | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

## Value

a pdCompSymm object representing a positive-definite matrix with compound symmetry structure, also inheriting from class pdMat.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. p. 161.

## See Also

as.matrix.pdMat, coef.pdMat, matrix<-.pdMat, pdClasses

## Examples

```
pd1 <- pdCompSymm(diag(3) + 1, nam = c("A","B","C"))
pd1
```

---

pdConstruct *Construct pdMat Objects*

---

## Description

This function is an alternative constructor for the pdMat class associated with object and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the pdMat class of object.

## Usage

```
pdConstruct(object, value, form, nam, data, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class pdMat, representing a positive definite matrix. |
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object. |
| form | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL. |
| nam | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL. |
| data | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| ... | optional arguments for some methods. |

## Value

a pdMat object representing a positive-definite matrix, inheriting from the same classes as object.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

pdCompSymm, pdDiag, pdIdent, pdNatural, pdSymm

## Examples

```
pd1 <- pdSymm()
pdConstruct(pd1, diag(1:4))
```

---

# pdConstruct.pdBlocked *Construct pdBlocked Objects*

---

## Description

This function give an alternative constructor for the pdBlocked class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual pdMat object. When value is numeric(0), a list of uninitialized pdMat objects, a list of one-sided formulas, or a list of vectors of character strings, object is returned as an uninitialized pdBlocked object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is a list of initialized pdMat objects, object will be constructed from the list obtained by applying as.matrix to each of the pdMat elements of value. Finally, if value is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

## Usage

```
## S3 method for class 'pdBlocked'
pdConstruct(object, value, form, nam, data, pdClass,
...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "pdBlocked", representing a positive definite block-diagonal matrix. |
| value | an optional list with elements to be used as the value argument to other pdMat constructors. These include: pdMat objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to numeric(0), corresponding to an uninitialized object. |
| form | an optional list of one-sided linear formula specifying the row/column names for the block-diagonal elements of the matrix represented by object. Because factors may be present in form, the formulas needs to be evaluated on a data.frame to resolve the names they defines. This argument is ignored when value is a list of one-sided formulas. Defaults to NULL. |
| nam | an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by object. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when value is a list of vector of character strings. Defaults to NULL. |

| | |
|---|---|
| data | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| pdClass | an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm". |
| ... | some methods for this generic require additional arguments. None are used in this method. |

## Value

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

## See Also

as.matrix.pdMat, coef.pdMat, pdBlocked, pdClasses, pdConstruct, matrix<-.pdMat

## Examples

```
pd1 <- pdBlocked(list(c("A","B"), c("a1", "a2", "a3")))
pdConstruct(pd1, list(diag(1:2), diag(c(0.1, 0.2, 0.3))))
```

---

# pdDiag *Diagonal Positive-Definite Matrix*

---

## Description

This function is a constructor for the pdDiag class, representing a diagonal positive-definite matrix. If the matrix associated with object is of dimension $n$, it is represented by $n$ unrestricted parameters, given by the logarithm of the square-root of the diagonal values. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdDiag object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

## Usage

```
pdDiag(value, form, nam, data)
```

### Arguments

| | |
|---|---|
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector of length equal to the dimension of the underlying positive-definite matrix. Defaults to numeric(0), corresponding to an uninitialized object. |
| form | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL. |
| nam | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL. |
| data | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

### Value

a pdDiag object representing a diagonal positive-definite matrix, also inheriting from class pdMat.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

### See Also

pd1 <- pdDiag(diag(1:3), nam = c("A","B","C"))
pd1
```

---

## pdFactor *Square-Root Factor of a Positive-Definite Matrix*

---

### Description

A square-root factor of the positive-definite matrix represented by object is obtained. Letting $\Sigma$ denote a positive-definite matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L'L$. This function extracts $L$.

### Usage

```
pdFactor(object)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `pdMat`, representing a positive definite matrix, which must have been initialized (i.e. `length(coef(object)) > 0`). |

### Value

a vector with a square-root factor of the positive-definite matrix associated with `object` stacked column-wise.

### Note

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `pdMatrix` function can be used to obtain square-root factors in matrix form.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

pd1 <- pdCompSymm(4 * diag(3) + 1)
pdFactor(pd1)
```

---

## pdFactor.reStruct *Extract Square-Root Factor from Components of an reStruct Object*

---

### Description

This method function extracts square-root factors of the positive-definite matrices corresponding to the `pdMat` elements of `object`.

### Usage

```
## S3 method for class 'reStruct'
pdFactor(object)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"reStruct"`, representing a random effects structure and consisting of a list of `pdMat` objects. |

## Value

a vector with square-root factors of the positive-definite matrices corresponding to the elements of `object` stacked column-wise.

## Note

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `pdMatrix` function can be used to obtain square-root factors in matrix form.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```
rs1 <- reStruct(pdSymm(diag(3), ~age+Sex, data = Orthodont))
pdFactor(rs1)
```

---

`pdIdent` *Multiple of the Identity Positive-Definite Matrix*

---

## Description

This function is a constructor for the `pdIdent` class, representing a multiple of the identity positive-definite matrix. The matrix associated with `object` is represented by 1 unrestricted parameter, given by the logarithm of the square-root of the diagonal value. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdIdent` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric value, it is assumed to represent the unrestricted coefficient of the underlying positive-definite matrix.

## Usage

```
pdIdent(value, form, nam, data)
```

### Arguments

| | |
|---|---|
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric value. Defaults to numeric(0), corresponding to an uninitialized object. |
| form | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL. |
| nam | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL. |
| data | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

### Value

a pdIdent object representing a multiple of the identity positive-definite matrix, also inheriting from class pdMat.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

## pdLogChol *General Positive-Definite Matrix*

---

## Description

This function is a constructor for the `pdLogChol` class, representing a general positive-definite matrix. If the matrix associated with `object` is of dimension $n$, it is represented by $n(n+1)/2$ unrestricted parameters, using the log-Cholesky parametrization described in Pinheiro and Bates (1996).

- When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a character vector, `object` is returned as an *uninitialized* `pdLogChol` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions.
- If `value` is an *initialized* `pdMat` object, `object` will be constructed from `as.matrix(value)`.
- Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

## Usage

```
pdLogChol(value, form, nam, data)
```

## Arguments

| | |
|---|---|
| `value` | an optional initialization value, which can be any of the following: a `pdMat` object, a positive-definite matrix, a one-sided linear formula (with variables separated by `+`), a vector of character strings, or a numeric vector. Defaults to `numeric(0)`, corresponding to an uninitialized object. |
| `form` | an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a data frame to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to `NULL`. |
| `nam` | an optional character vector specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when `value` is a character vector. Defaults to `NULL`. |
| `data` | an optional data frame in which to evaluate the variables named in `value` and `form`. It is used to obtain the levels for `factors`, which affect the dimensions and the row/column names of the underlying matrix. If `NULL`, no attempt is made to obtain information on `factors` appearing in the formulas. Defaults to the parent frame from which the function was called. |

## Details

Internally, the `pdLogChol` representation of a symmetric positive definite matrix is a vector starting with the logarithms of the diagonal of the Choleski factorization of that matrix followed by its upper triangular portion.

## Value

a `pdLogChol` object representing a general positive-definite matrix, also inheriting from class `pdMat`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
(pd1 <- pdLogChol(diag(1:3), nam = c("A","B","C")))

(pd4 <- pdLogChol(1:6))
(pd4c <- chol(pd4)) # -> upper-tri matrix with off-diagonals  4 5 6
pd4c[upper.tri(pd4c)]
log(diag(pd4c)) # 1 2 3
```

---

`pdMat` *Positive-Definite Matrix*

---

## Description

This function gives an alternative way of constructing an object inheriting from the `pdMat` class named in `pdClass`, or from `data.class(object)` if `object` inherits from `pdMat`, and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the `pdMat` class of object.

## Usage

```
pdMat(value, form, nam, data, pdClass)
```

## Arguments

| | |
|---|---|
| `value` | an optional initialization value, which can be any of the following: a `pdMat` object, a positive-definite matrix, a one-sided linear formula (with variables separated by `+`), a vector of character strings, or a numeric vector. Defaults to `numeric(0)`, corresponding to an uninitialized object. |
| `form` | an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to `NULL`. |
| `nam` | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when `value` is a vector of character strings. Defaults to `NULL`. |
| `data` | an optional data frame in which to evaluate the variables named in `value` and `form`. It is used to obtain the levels for `factors`, which affect the dimensions and the row/column names of the underlying matrix. If `NULL`, no attempt is made to obtain information on `factors` appearing in the formulas. Defaults to the parent frame from which the function was called. |

pdClass — an optional character string naming the pdMat class to be assigned to the returned object. This argument will only be used when value is not a pdMat object. Defaults to "pdSymm".

## Value

a pdMat object representing a positive-definite matrix, inheriting from the class named in pdClass, or from class(object), if object inherits from pdMat.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

## Examples

```
pd1 <- pdMat(diag(1:4), pdClass = "pdDiag")
pd1
```

---

# pdMatrix — *Extract Matrix or Square-Root Factor from a pdMat Object*

---

## Description

The positive-definite matrix represented by object, or a square-root factor of it is obtained. Letting $\Sigma$ denote a positive-definite matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L'L$. This function extracts $S$ or $L$.

## Usage

```
pdMatrix(object, factor)
```

## Arguments

object — an object inheriting from class pdMat, representing a positive definite matrix.

factor — an optional logical value. If TRUE, a square-root factor of the positive-definite matrix represented by object is returned; else, if FALSE, the positive-definite matrix is returned. Defaults to FALSE.

## Value

if fact is FALSE the positive-definite matrix represented by object is returned; else a square-root of the positive-definite matrix is returned.

pdNatural *General Positive-Definite Matrix in Natural Parametrization*

---

## Description

This function is a constructor for the pdNatural class, representing a general positive-definite matrix, using a natural parametrization . If the matrix associated with object is of dimension $n$, it is represented by $n(n+1)/2$ parameters. Letting $\sigma_{ij}$ denote the $ij$-th element of the underlying positive definite matrix and $\rho_{ij} = \sigma_i/\sqrt{\sigma_{ii}\sigma_{jj}},\ i \neq j$ denote the associated "correlations", the "natural" parameters are given by $\sqrt{\sigma_{ii}},\ i = 1, \ldots, n$ and $\log((1+\rho_{ij})/(1-\rho_{ij})),\ i \neq j$. Note that all natural parameters are individually unrestricted, but not jointly unrestricted (meaning that not all unrestricted vectors would give positive-definite matrices). Therefore, this parametrization should NOT be used for optimization. It is mostly used for deriving approximate confidence intervals on parameters following the optimization of an objective function. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdSymm object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector, it is assumed to represent the natural parameters of the underlying positive-definite matrix.

## Usage

```
pdNatural(value, form, nam, data)
```

## Arguments

| | |
|---|---|
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object. |
| form | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL. |
| nam | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL. |
| data | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

### Value

a pdNatural object representing a general positive-definite matrix in natural parametrization, also inheriting from class pdMat.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. p. 162.

```
pdNatural(diag(1:3))
```

---

## pdSymm *General Positive-Definite Matrix*

---

### Description

This function is a constructor for the pdSymm class, representing a general positive-definite matrix. If the matrix associated with object is of dimension $n$, it is represented by $n(n+1)/2$ unrestricted parameters, using the matrix-logarithm parametrization described in Pinheiro and Bates (1996). When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdSymm object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

### Usage

```
pdSymm(value, form, nam, data)
```

### Arguments

| | |
|---|---|
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object. |
| form | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL. |

nam — an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.

data — an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

## Value

a pdSymm object representing a general positive-definite matrix, also inheriting from class pdMat.

Phenobarb *Phenobarbitol Kinetics*

---

## Description

The Phenobarb data frame has 744 rows and 7 columns.

## Format

This data frame contains the following columns:

**Subject** an ordered factor identifying the infant.

**Wt** a numeric vector giving the birth weight of the infant (kg).

**Apgar** an ordered factor giving the 5-minute Apgar score for the infant. This is an indication of health of the newborn infant.

**ApgarInd** a factor indicating whether the 5-minute Apgar score is < 5 or >= 5.

**time** a numeric vector giving the time when the sample is drawn or drug administered (hr).

**dose** a numeric vector giving the dose of drug administered ($u$g/kg).

**conc** a numeric vector giving the phenobarbital concentration in the serum ($u$g/L).

## Details

Data from a pharmacokinetics study of phenobarbital in neonatal infants. During the first few days of life the infants receive multiple doses of phenobarbital for prevention of seizures. At irregular intervals blood samples are drawn and serum phenobarbital concentrations are determined. The data were originally given in Grasela and Donn(1985) and are analyzed in Boeckmann, Sheiner and Beal (1994), in Davidian and Giltinan (1995), and in Littell et al. (1996).

`phenoModel` *Model function for the Phenobarb data*

---

## Description

A model function for a model used with the `Phenobarb` data. This function uses compiled C code to improve execution speed.

## Usage

```
phenoModel(Subject, time, dose, lCl, lV)
```

## Arguments

| | |
|---|---|
| `Subject` | an integer vector of subject identifiers. These should be sorted in increasing order. |
| `time` | numeric. A vector of the times at which the sample was drawn or the drug administered (hr). |
| `dose` | numeric. A vector of doses of drug administered ($u$g/kg). |
| `lCl` | numeric. A vector of values of the natural log of the clearance parameter according to `Subject` and `time`. |
| `lV` | numeric. A vector of values of the natural log of the effective volume of distribution according to `Subject` and `time`. |

## Details

See the details section of `Phenobarb` for a description of the model function that `phenoModel` evaluates.

### Value

a numeric vector of predicted phenobarbital concentrations.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J. C. and Bates, D. M. (2000) *Mixed-effects Models in S and S-PLUS*, Springer. (section 6.4)

## Pixel — *X-ray pixel intensities over time*

---

### Description

The `Pixel` data frame has 102 rows and 4 columns of data on the pixel intensities of CT scans of dogs over time

### Format

This data frame contains the following columns:

**Dog** a factor with levels `1` to `10` designating the dog on which the scan was made

**Side** a factor with levels `L` and `R` designating the side of the dog being scanned

**day** a numeric vector giving the day post injection of the contrast on which the scan was made

**pixel** a numeric vector of pixel intensities

### Source

Pinheiro, J. C. and Bates, D. M. (2000) *Mixed-effects Models in S and S-PLUS*, Springer.

### Examples

```
fm1 <- lme(pixel ~ day + I(day^2), data = Pixel,
           random = list(Dog = ~ day, Side = ~ 1))
summary(fm1)
VarCorr(fm1)
```

plot.ACF *Plot an ACF Object*

## Description

an xyplot of the autocorrelations versus the lags, with type = "h", is produced. If alpha > 0, curves representing the critical limits for a two-sided test of level alpha for the autocorrelations are added to the plot.

## Usage

```
## S3 method for class 'ACF'
plot(x, alpha, xlab, ylab, grid, ...)
```

## Arguments

| | |
|---|---|
| x | an object inheriting from class ACF, consisting of a data frame with two columns named lag and ACF, representing the autocorrelation values and the corresponding lags. |
| alpha | an optional numeric value with the significance level for testing if the autocorrelations are zero. Lines corresponding to the lower and upper critical values for a test of level alpha are added to the plot. Default is 0, in which case no lines are plotted. |
| xlab,ylab | optional character strings with the x- and y-axis labels. Default respectively to "Lag" and "Autocorrelation". |
| grid | an optional logical value indicating whether a grid should be added to plot. Default is FALSE. |
| ... | optional arguments passed to the xyplot function. |

## Value

an xyplot Trellis plot.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

ACF, xyplot

## Examples

```
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
plot(ACF(fm1, maxLag = 10), alpha = 0.01)
```

plot.augPred *Plot an augPred Object*

## Description

A Trellis xyplot of predictions versus the primary covariate is generated, with a different panel for each value of the grouping factor. Predicted values are joined by lines, with different line types (colors) being used for each level of grouping. Original observations are represented by circles.

## Usage

```
## S3 method for class 'augPred'
plot(x, key, grid, ...)
```

## Arguments

| | |
|---|---|
| x | an object of class "augPred". |
| key | an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the trellis function generating the plots (xyplot). Defaults to TRUE. |
| grid | an optional logical value indicating whether a grid should be added to plot. Default is FALSE. |
| ... | optional arguments passed down to the trellis function generating the plots. |

## Value

A Trellis plot of predictions versus the primary covariate, with panels determined by the grouping factor.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

augPred, xyplot

## Examples

```
fm1 <- lme(Orthodont)
plot(augPred(fm1, level = 0:1, length.out = 2))
```

## plot.compareFits *Plot a compareFits Object*

### Description

A Trellis `dotplot` of the values being compared, with different rows per group, is generated, with a different panel for each coefficient. Different symbols (colors) are used for each object being compared.

### Usage

```
## S3 method for class 'compareFits'
plot(x, subset, key, mark, ...)
```

### Arguments

| | |
|---|---|
| `x` | an object of class "`compareFits`". |
| `subset` | an optional logical or integer vector specifying which rows of `x` should be used in the plots. If missing, all rows are used. |
| `key` | an optional logical value, or list. If `TRUE`, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If `FALSE`, no legend is included. If given as a list, `key` is passed down as an argument to the `trellis` function generating the plots (`dotplot`). Defaults to `TRUE`. |
| `mark` | an optional numeric vector, of length equal to the number of coefficients being compared, indicating where vertical lines should be drawn in the plots. If missing, no lines are drawn. |
| `...` | optional arguments passed down to the `trellis` function generating the plots. |

### Value

A Trellis `dotplot` of the values being compared, with rows determined by the groups and panels by the coefficients.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`compareFits`, `pairs.compareFits`, `dotplot`

### Examples

```
## Not run:
fm1 <- lmList(Orthodont)
fm2 <- lme(Orthodont)
plot(compareFits(coef(fm1), coef(fm2)))

## End(Not run)
```

plot.gls *Plot a gls Object*

## Description

Diagnostic plots for the linear model fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left had side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

## Usage

```
## S3 method for class 'gls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```

## Arguments

| | |
|---|---|
| `x` | an object inheriting from class "`gls`", representing a generalized least squares fitted linear model. |
| `form` | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain `x` can be referenced. In addition, `x` itself can be referenced in the formula using the symbol "`.`". Conditional expressions on the right of a `|` operator can be used to define separate panels in a Trellis display. Default is `resid(., type = "p") ~ fitted(.)` , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting. |
| `abline` | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot. |
| `id` | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using `idLabels`. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified. |
| `idLabels` | an optional vector, or one-sided formula. If given as a vector, it is converted to character mode and used to label the observations identified according to `id`. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character mode and used to label the identified observations. Default is the innermost grouping factor. |
| `idResType` | an optional character string specifying the type of residuals to be used in identifying outliers, when `id` is a numeric value. If "`pearson`", the standardized |

residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

grid — an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

... — optional arguments passed to the Trellis plot function.

## Value

a diagnostic Trellis plot.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

gls, xyplot, bwplot, histogram

## Examples

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
# standardized residuals versus fitted values by Mare
plot(fm1, resid(., type = "p") ~ fitted(.) | Mare, abline = 0)
# box-plots of residuals by Mare
plot(fm1, Mare ~ resid(.))
# observed versus fitted values by Mare
plot(fm1, follicles ~ fitted(.) | Mare, abline = c(0,1))
```

---

# plot.intervals.lmList *Plot lmList Confidence Intervals*

---

## Description

A Trellis dot-plot of the confidence intervals on the linear model coefficients is generated, with a different panel for each coefficient. Rows in the dot-plot correspond to the names of the lm components of the lmList object used to produce x. The lower and upper confidence limits are connected by a line segment and the estimated coefficients are marked with a "+". The Trellis function dotplot is used in this method function.

## Usage

```
## S3 method for class 'intervals.lmList'
plot(x, ...)
```

### Arguments

| | |
|---|---|
| x | an object inheriting from class "intervals.lmList", representing confidence intervals and estimates for the coefficients in the lm components of the lmList object used to produce x. |
| ... | optional arguments passed to the Trellis dotplot function. |

### Value

a Trellis plot with the confidence intervals on the coefficients of the individual lm components of the lmList that generated x.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

intervals.lmList, lmList, dotplot

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
plot(intervals(fm1))
```

---

## plot.lme *Plot an lme or nls object*

---

### Description

Diagnostic plots for the linear mixed-effects fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If form is a one-sided formula, histograms of the variable on the right hand side of the formula, before a | operator, are displayed (the Trellis function histogram is used). If form is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function xyplot is used). Finally, if form is two-sided and its left had side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function bwplot is used).

### Usage

```
## S3 method for class 'lme'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
## S3 method for class 'nls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```

## Arguments

| | |
|---|---|
| x | an object inheriting from class "lme", representing a fitted linear mixed-effects model, or from nls, representing an fitted nonlinear least squares model. |
| form | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ". ". Conditional expressions on the right of a \| operator can be used to define separate panels in a Trellis display. Default is resid(., type = "p") ~ fitted(.) , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting. |
| abline | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot. |
| id | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized, or normalized residuals. Observations with absolute standardized (normalized) residuals greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified. |
| idLabels | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor. |
| idResType | an optional character string specifying the type of residuals to be used in identifying outliers, when id is a numeric value. If "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals premultiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson". |
| grid | an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE. |
| ... | optional arguments passed to the Trellis plot function. |

## Value

a diagnostic Trellis plot.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

lme, xyplot, bwplot, histogram

## Examples

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
# standardized residuals versus fitted values by gender
plot(fm1, resid(., type = "p") ~ fitted(.) | Sex, abline = 0)
# box-plots of residuals by Subject
plot(fm1, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fm1, distance ~ fitted(.) | Subject, abline = c(0,1))
```

---

# plot.lmList *Plot an lmList Object*

---

## Description

Diagnostic plots for the linear model fits corresponding to the `x` components are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left had side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

## Usage

```
## S3 method for class 'lmList'
plot(x, form, abline, id, idLabels, grid, ...)
```

## Arguments

| | |
|---|---|
| `x` | an object inheriting from class `"lmList"`, representing a list of `lm` objects with a common model. |
| `form` | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain `x` can be referenced. In addition, `x` itself can be referenced in the formula using the symbol `"."`. Conditional expressions on the right of a `|` operator can be used to define separate panels in a Trellis display. Default is `resid(., type = "pool") ~ fitted(.)` , corresponding to a plot of the standardized residuals (using a pooled estimate for the residual standard error) versus fitted values. |
| `abline` | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot. |
| `id` | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using `idLabels`. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified. |

| | |
|---|---|
| idLabels | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is getGroups(x). |
| grid | an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE. |
| ... | optional arguments passed to the Trellis plot function. |

## Value

a diagnostic Trellis plot.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

lmList,predict.lm, xyplot, bwplot, histogram

## Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
# standardized residuals versus fitted values by gender
plot(fm1, resid(., type = "pool") ~ fitted(.) | Sex, abline = 0, id = 0.05)
# box-plots of residuals by Subject
plot(fm1, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fm1, distance ~ fitted(.) | Subject, abline = c(0,1))
```

---

# plot.nffGroupedData *Plot an nffGroupedData Object*

---

## Description

A Trellis dot-plot of the response by group is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. The Trellis function dotplot is used.

## Usage

```
## S3 method for class 'nffGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, panel, key,
     grid, ...)
```

### Arguments

| | |
|---|---|
| x | an object inheriting from class nffGroupedData, representing a groupedData object with a factor primary covariate and a single grouping level. |
| outer | an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to TRUE, attr(object, "outer") is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used. |
| inner | an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to TRUE, attr(object, "inner") is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present. |
| innerGroups | an optional one-sided formula specifying a factor to be used for grouping the levels of the inner covariate. Different colors, or symbols, are used for each level of the innerGroups factor. Default is NULL, meaning that no innerGroups covariate is present. |
| xlab | an optional character string with the label for the horizontal axis. Default is the y elements of attr(object, "labels") and attr(object, "units") pasted together. |
| ylab | an optional character string with the label for the vertical axis. Default is the grouping factor name. |
| strip | an optional function passed as the strip argument to the dotplot function. Default is strip.default(..., style = 1) (see trellis.args). |
| panel | an optional function used to generate the individual panels in the Trellis display, passed as the panel argument to the dotplot function. |
| key | an optional logical function or function. If TRUE and either inner or innerGroups are non-NULL, a legend for the different inner (innerGroups) levels is included at the top of the plot. If given as a function, it is passed as the key argument to the dotplot function. Default is TRUE is either inner or innerGroups are non-NULL and FALSE otherwise. |
| grid | this argument is included for consistency with the plot.nfnGroupedData method calling sequence. It is ignored in this method function. |
| ... | optional arguments passed to the dotplot function. |

### Value

a Trellis dot-plot of the response by group.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Bates, D.M. and Pinheiro, J.C. (1997), "Software Design for Longitudinal Data", in "Modelling Longitudinal and Spatially Correlated Data: Methods, Applications and Future Directions", T.G. Gregoire (ed.), Springer-Verlag, New York.

### See Also

groupedData, dotplot

### Examples

```
plot(Machines)
plot(Machines, inner = TRUE)
```

---

## plot.nfnGroupedData *Plot an nfnGroupedData Object*

---

### Description

A Trellis plot of the response versus the primary covariate is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. Otherwise, the levels of the grouping variable determine the panels. A scatter plot of the response versus the primary covariate is displayed in each panel, with observations corresponding to same inner group joined by line segments. The Trellis function `xyplot` is used.

### Usage

```
## S3 method for class 'nfnGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, aspect, panel,
     key, grid, ...)
```

### Arguments

| | |
|---|---|
| `x` | an object inheriting from class `nfnGroupedData`, representing a `groupedData` object with a numeric primary covariate and a single grouping level. |
| `outer` | an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to `TRUE`, `attr(object, "outer")` is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to `NULL`, meaning that no outer covariates are to be used. |
| `inner` | an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to `TRUE`, `attr(object, "inner")` is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to `NULL`, meaning that no inner covariate is present. |
| `innerGroups` | an optional one-sided formula specifying a factor to be used for grouping the levels of the `inner` covariate. Different colors, or line types, are used for each level of the `innerGroups` factor. Default is `NULL`, meaning that no `innerGroups` covariate is present. |
| `xlab, ylab` | optional character strings with the labels for the plot. Default is the corresponding elements of `attr(object, "labels")` and `attr(object, "units")` pasted together. |

| | |
|---|---|
| strip | an optional function passed as the strip argument to the xyplot function. Default is strip.default(..., style = 1) (see trellis.args). |
| aspect | an optional character string indicating the aspect ratio for the plot passed as the aspect argument to the xyplot function. Default is "xy" (see trellis.args). |
| panel | an optional function used to generate the individual panels in the Trellis display, passed as the panel argument to the xyplot function. |
| key | an optional logical function or function. If TRUE and innerGroups is non-NULL, a legend for the different innerGroups levels is included at the top of the plot. If given as a function, it is passed as the key argument to the xyplot function. Default is TRUE if innerGroups is non-NULL and FALSE otherwise. |
| grid | an optional logical value indicating whether a grid should be added to plot. Default is TRUE. |
| ... | optional arguments passed to the xyplot function. |

## Value

a Trellis plot of the response versus the primary covariate.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Bates, D.M. and Pinheiro, J.C. (1997), "Software Design for Longitudinal Data", in "Modelling Longitudinal and Spatially Correlated Data: Methods, Applications and Future Directions", T.G. Gregoire (ed.), Springer-Verlag, New York.

## See Also

groupedData, xyplot

## Examples

```
# different panels per Subject
plot(Orthodont)
# different panels per gender
plot(Orthodont, outer = TRUE)
```

---

# plot.nmGroupedData *Plot an nmGroupedData Object*

---

## Description

The groupedData object is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor, which is plotted using the appropriate plot method for groupedData objects with single level of grouping.

### Usage

```
## S3 method for class 'nmGroupedData'
plot(x, collapseLevel, displayLevel, outer, inner,
    preserve, FUN, subset, key, grid, ...)
```

### Arguments

| | |
|---|---|
| x | an object inheriting from class nmGroupedData, representing a groupedData object with multiple grouping factors. |
| collapseLevel | an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping. |
| displayLevel | an optional positive integer or character string indicating the grouping level to use for determining the panels in the Trellis display, when outer is missing. Default is collapseLevel. |
| outer | an optional logical value or one-sided formula, indicating covariates that are outer to the displayLevel grouping factor, which are used to determine the panels of the Trellis plot. If equal to TRUE, the displayLevel element attr(object, "outer") is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used. |
| inner | an optional logical value or one-sided formula, indicating a covariate that is inner to the displayLevel grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to TRUE, attr(object, "outer") is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present. |
| preserve | an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the collapseLevel grouping factor. The collapsing factor is obtained by pasting together the levels of the collapseLevel grouping factor and the values of the covariate to be preserved. Default is NULL, meaning that no covariates need to be preserved. |
| FUN | an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by collapseLevel. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the data such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable. |
| subset | an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be used for plotting the data. Default is NULL, meaning that all levels are used. |

| | |
|---|---|
| key | an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the trellis function generating the plots (xyplot). Defaults to TRUE. |
| grid | an optional logical value indicating whether a grid should be added to plot. Default is TRUE. |
| ... | optional arguments passed to the Trellis plot function. |

## Value

a Trellis display of the data collapsed over the values of the collapseLevel grouping factor and grouped according to the displayLevel grouping factor.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
# no collapsing, panels by Dog
plot(Pixel, display = "Dog", inner = ~Side)
# collapsing by Dog, preserving day
plot(Pixel, collapse = "Dog", preserve = ~day)
```

---

# plot.ranef.lme *Plot a ranef.lme Object*

---

## Description

If form is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the form argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in form, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if form specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function dotplot is used in this method function.

If form is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of form. Scatter plots are generated for numeric variables and boxplots are generated for categorical (factor or ordered) variables.

## Usage

```
## S3 method for class 'ranef.lme'
plot(x, form, omitFixed, level, grid, control, ...)
```

## Arguments

| | |
|---|---|
| `x` | an object inheriting from class "`ranef.lme`", representing the estimated coefficients or estimated random effects for the `lme` object from which it was produced. |
| `form` | an optional formula specifying the desired type of plot. If given as a one-sided formula, a `dotplot` of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in `form` is returned. Single factors (`~g`) or crossed factors (`~g1*g2`) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in `x` separated by `+`. A Trellis display of the random effect (coefficient) versus the named covariates is returned in this case. Default is `NULL`, in which case the row names of the random effects (coefficients) are used. |
| `omitFixed` | an optional logical value indicating whether columns with values that are constant across groups should be omitted. Default is `TRUE`. |
| `level` | an optional integer value giving the level of grouping to be used for `x`. Only used when `x` is a list with different components for each grouping level. Defaults to the highest or innermost level of grouping. |
| `grid` | an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in `form`. Default is `FALSE`. |
| `control` | an optional list with control values for the plot, when `form` is given as a two-sided formula. The control values are referenced by name in the `control` list and only the ones to be modified from the default need to be specified. Available values include: `drawLine`, a logical value indicating whether a `loess` smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is `TRUE`); `span.loess`, used as the `span` argument in the call to `panel.loess` (default is `2/3`); `degree.loess`, used as the `degree` argument in the call to `panel.loess` (default is `1`); `cex.axis`, the character expansion factor for the x-axis (default is `0.8`); `srt.axis`, the rotation factor for the x-axis (default is `0`); and `mgp.axis`, the margin parameters for the x-axis (default is `c(2, 0.5, 0)`). |
| `...` | optional arguments passed to the Trellis `dotplot` function. |

## Value

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

plot(ranef(fm1))
fm1RE <- ranef(fm1, aug = TRUE)
plot(fm1RE, form = ~ Sex)
plot(fm1RE, form = age ~ Sex)

## End(Not run)
```

---

`plot.ranef.lmList` *Plot a ranef.lmList Object*

---

## Description

If `form` is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the `form` argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in `form`, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if `form` specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function `dotplot` is used in this method function.

If `form` is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of `form`. Scatter plots are generated for numeric variables and boxplots are generated for categorical (`factor` or `ordered`) variables.

## Usage

```
## S3 method for class 'ranef.lmList'
plot(x, form, grid, control, ...)
```

## Arguments

| | |
|---|---|
| `x` | an object inheriting from class "`ranef.lmList`", representing the estimated coefficients or estimated random effects for the `lmList` object from which it was produced. |
| `form` | an optional formula specifying the desired type of plot. If given as a one-sided formula, a `dotplot` of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in `form` is returned. Single factors (`~g`) or crossed factors (`~g1*g2`) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in `x` separated by `+`. A Trellis display of the random effect (coefficient) versus the named covariates is returned in this case. Default is `NULL`, in which case the row names of the random effects (coefficients) are used. |
| `grid` | an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in `form`. Default is `FALSE`. |
| `control` | an optional list with control values for the plot, when `form` is given as a two-sided formula. The control values are referenced by name in the `control` list and only the ones to be modified from the default need to be specified. Available |

values include: drawLine, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is TRUE); span.loess, used as the span argument in the call to panel.loess (default is 2/3); degree.loess, used as the degree argument in the call to panel.loess (default is 1); cex.axis, the character expansion factor for the x-axis (default is 0.8); srt.axis, the rotation factor for the x-axis (default is 0); and mgp.axis, the margin parameters for the x-axis (default is c(2, 0.5, 0)).

... optional arguments passed to the Trellis dotplot function.

## Value

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

lmList, dotplot

## Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
plot(ranef(fm1))

plot(fm1RE, form = ~ Sex)
## Not run: plot(fm1RE, form = age ~ Sex)
```

---

# plot.Variogram *Plot a Variogram Object*

---

## Description

an xyplot of the semi-variogram versus the distances is produced. If smooth = TRUE, a loess smoother is added to the plot. If showModel = TRUE and x includes an "modelVariog" attribute, the corresponding semi-variogram is added to the plot.

## Usage

```
## S3 method for class 'Variogram'
plot(x, smooth, showModel, sigma, span, xlab,
     ylab, type, ylim, grid, ...)
```

## Arguments

x an object inheriting from class "Variogram", consisting of a data frame with two columns named variog and dist, representing the semi-variogram values and the corresponding distances.

smooth an optional logical value controlling whether a loess smoother should be added to the plot. Defaults to TRUE, when showModel is FALSE.

| | |
|---|---|
| showModel | an optional logical value controlling whether the semi-variogram corresponding to an "modelVariog" attribute of x, if any is present, should be added to the plot. Defaults to TRUE, when the "modelVariog" attribute is present. |
| sigma | an optional numeric value used as the height of a horizontal line displayed in the plot. Can be used to represent the process standard deviation. Default is NULL, implying that no horizontal line is drawn. |
| span | an optional numeric value with the smoothing parameter for the loess fit. Default is 0.6. |
| xlab,ylab | optional character strings with the x- and y-axis labels. Default respectively to "Distance" and "SemiVariogram". |
| type | an optional character indicating the type of plot. Defaults to "p". |
| ylim | an optional numeric vector with the limits for the y-axis. Defaults to c(0, max(x$variog)). |
| grid | an optional logical value indicating whether a grid should be added to plot. Default is FALSE. |
| ... | optional arguments passed to the Trellis xyplot function. |

## Value

an xyplot Trellis plot.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

Variogram, xyplot, loess

## Examples

```
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
plot(Variogram(fm1, form = ~ Time | Mare, maxDist = 0.7))
```

---

# pooledSD *Extract Pooled Standard Deviation*

---

## Description

The pooled estimated standard deviation is obtained by adding together the residual sum of squares for each non-null element of object, dividing by the sum of the corresponding residual degrees-of-freedom, and taking the square-root.

## Usage

```
pooledSD(object)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class lmList. |

### Value

the pooled standard deviation for the non-null elements of `object`, with an attribute `df` with the number of degrees-of-freedom used in the estimation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

### Examples

```
fm1 <- lmList(Orthodont)
pooledSD(fm1)
```

---

## predict.gls *Predictions from a gls Object*

---

### Description

The predictions for the linear model represented by `object` are obtained at the covariate values defined in `newdata`.

### Usage

```
## S3 method for class 'gls'
predict(object, newdata, na.action, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`gls`", representing a generalized least squares fitted linear model. |
| `newdata` | an optional data frame to be used for obtaining the predictions. All variables used in the linear model must be present in the data frame. If missing, the fitted values are returned. |
| `na.action` | a function that indicates what should happen when `newdata` contains `NA`s. The default action (`na.fail`) causes the function to print an error message and terminate if there are any incomplete observations. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

a vector with the predicted values.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

gls

## Examples

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
newOvary <- data.frame(Time = c(-0.75, -0.5, 0, 0.5, 0.75))
predict(fm1, newOvary)
```

---

# predict.gnls *Predictions from a gnls Object*

---

## Description

The predictions for the nonlinear model represented by `object` are obtained at the covariate values defined in `newdata`.

## Usage

```
## S3 method for class 'gnls'
predict(object, newdata, na.action, naPattern, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class "gnls", representing a generalized nonlinear least squares fitted model. |
| `newdata` | an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model must be present in the data frame. If missing, the fitted values are returned. |
| `na.action` | a function that indicates what should happen when `newdata` contains `NA`s. The default action (`na.fail`) causes the function to print an error message and terminate if there are any incomplete observations. |
| `naPattern` | an expression or formula object, specifying which returned values are to be regarded as missing. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

a vector with the predicted values.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

gnls

## Examples

```
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
            weights = varPower())
newSoybean <- data.frame(Time = c(10,30,50,80,100))
predict(fm1, newSoybean)
```

---

`predict.lme` *Predictions from an lme Object*

---

## Description

The predictions at level $i$ are obtained by adding together the population predictions (based only on the fixed effects estimates) and the estimated contributions of the random effects to the predictions at grouping levels less or equal to $i$. The resulting values estimate the best linear unbiased predictions (BLUPs) at level $i$. If group values not included in the original grouping factors are present in `newdata`, the corresponding predictions will be set to `NA` for levels greater or equal to the level at which the unknown groups occur.

## Usage

```
## S3 method for class 'lme'
predict(object, newdata, level = Q, asList = FALSE,
        na.action = na.fail, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`lme`", representing a fitted linear mixed-effects model. |
| `newdata` | an optional data frame to be used for obtaining the predictions. All variables used in the fixed and random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned. |
| `level` | an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping. |
| `asList` | an optional logical value. If `TRUE` and a single value is given in `level`, the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of `level`. |
| `na.action` | a function that indicates what should happen when `newdata` contains `NA`s. The default action (`na.fail`) causes the function to print an error message and terminate if there are any incomplete observations. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

if a single level of grouping is specified in `level`, the returned value is either a list with the predictions split by groups (`asList = TRUE`) or a vector with the predictions (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

lme, fitted.lme

### Examples

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
newOrth <- data.frame(Sex = c("Male","Male","Female","Female","Male","Male"),
                      age = c(15, 20, 10, 12, 2, 4),
                      Subject = c("M01","M01","F30","F30","M04","M04"))
## The 'Orthodont' data has *no* 'F30', so predict  NA  at level 1 :
predict(fm1, newOrth, level = 0:1)
```

---

## predict.lmList *Predictions from an lmList Object*

---

### Description

If the grouping factor corresponding to object is included in newdata, the data frame is partitioned according to the grouping factor levels; else, newdata is repeated for all lm components. The predictions and, optionally, the standard errors for the predictions, are obtained for each lm component of object, using the corresponding element of the partitioned newdata, and arranged into a list with as many components as object, or combined into a single vector or data frame (if se.fit=TRUE).

### Usage

```
## S3 method for class 'lmList'
predict(object, newdata, subset, pool, asList, se.fit, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "lmList", representing a list of lm objects with a common model. |
| newdata | an optional data frame to be used for obtaining the predictions. All variables used in the object model formula must be present in the data frame. If missing, the same data frame used to produce object is used. |
| subset | an optional character or integer vector naming the lm components of object from which the predictions are to be extracted. Default is NULL, in which case all components are used. |
| asList | an optional logical value. If TRUE, the returned object is a list with the predictions split by groups; else the returned value is a vector. Defaults to FALSE. |
| pool | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object, "pool"). |
| se.fit | an optional logical value indicating whether pointwise standard errors should be computed along with the predictions. Default is FALSE. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

a list with components given by the predictions (and, optionally, the standard errors for the predictions) from each `lm` component of `object`, a vector with the predictions from all `lm` components of `object`, or a data frame with columns given by the predictions and their corresponding standard errors.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

fm1 <- lmList(distance ~ age | Subject, Orthodont)
predict(fm1, se.fit = TRUE)
```

---

## predict.nlme *Predictions from an nlme Object*

---

### Description

The predictions at level $i$ are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to $i$ and evaluating the model function at the resulting estimated parameters. If group values not included in the original grouping factors are present in `newdata`, the corresponding predictions will be set to `NA` for levels greater or equal to the level at which the unknown groups occur.

### Usage

```
## S3 method for class 'nlme'
predict(object, newdata, level = Q, asList = FALSE,
        na.action = na.fail, naPattern = NULL, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`nlme`", representing a fitted nonlinear mixed-effects model. |
| `newdata` | an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model, the fixed and the random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned. |
| `level` | an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping (and is `object$dims$Q`). |
| `asList` | an optional logical value. If `TRUE` and a single value is given in `level`, the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of `level`. |

| | |
|---|---|
| na.action | a function that indicates what should happen when newdata contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations. |
| naPattern | an expression or formula object, specifying which returned values are to be regarded as missing. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

## Value

if a single level of grouping is specified in level, the returned value is either a list with the predictions split by groups (asList = TRUE) or a vector with the predictions (asList = FALSE); else, when multiple grouping levels are specified in level, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

newLL.329 <- data.frame(age = age., Seed = 329)
(p301 <- predict(fm1, newLL.301, level = 0:1))
(p329 <- predict(fm1, newLL.329, level = 0:1))
## Prediction are the same at level 0 :
all.equal(p301[,"predict.fixed"],
          p329[,"predict.fixed"])
## and differ by the 'Seed' effect at level 1 :
p301[,"predict.Seed"] -
p329[,"predict.Seed"]
```

## print.summary.pdMat *Print a summary.pdMat Object*

### Description

The standard deviations and correlations associated with the positive-definite matrix represented by `object` (considered as a variance-covariance matrix) are printed, together with the formula and the grouping level associated `object`, if any are present.

### Usage

```
## S3 method for class 'summary.pdMat'
print(x, sigma, rdig, Level, resid, ...)
```

### Arguments

| | |
|---|---|
| `x` | an object inheriting from class "`summary.pdMat`", generally resulting from applying `summary` to an object inheriting from class "`pdMat`". |
| `sigma` | an optional numeric value used as a multiplier for the square-root factor of the positive-definite matrix represented by `object` (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1. |
| `rdig` | an optional integer value with the number of significant digits to be used in printing correlations. Defaults to 3. |
| `Level` | an optional character string with a description of the grouping level associated with `object` (generally corresponding to levels of grouping in a mixed-effects model). Defaults to NULL. |
| `resid` | an optional logical value. If `TRUE` an extra row with the "`residual`" standard deviation given in `sigma` will be included in the output. Defaults to `FALSE`. |
| `...` | optional arguments passed to `print.default`; see the documentation on that method function. |

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`summary.pdMat`,`pdMat`

### Examples

```
pd1 <- pdCompSymm(3 * diag(2) + 1, form = ~age + age^2,
         data = Orthodont)
print(summary(pd1), sigma = 1.2, resid = TRUE)
```

## print.varFunc — *Print a varFunc Object*

### Description

The class and the coefficients associated with x are printed.

### Usage

```
## S3 method for class 'varFunc'
print(x, ...)
```

### Arguments

| | |
|---|---|
| x | an object inheriting from class "varFunc", representing a variance function structure. |
| ... | optional arguments passed to print.default; see the documentation on that method function. |

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

summary.varFunc

### Examples

```
vf1 <- varPower(0.3, form = ~age)
vf1 <- Initialize(vf1, Orthodont)
print(vf1)
```

## qqnorm.gls — *Normal Plot of Residuals from a gls Object*

### Description

Diagnostic plots for assessing the normality of residuals the generalized least squares fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

### Usage

```
## S3 method for class 'gls'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

## Arguments

| | |
|---|---|
| y | an object inheriting from class "gls", representing a generalized least squares fitted model. |
| form | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain y can be referenced. In addition, y itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a \| operator can be used to define separate panels in a Trellis display. The expression on the right hand side of form and to the left of a \| operator must evaluate to a residuals vector. Default is ~ resid(., type = "p"), corresponding to a normal plot of the standardized residuals. |
| abline | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot. |
| id | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified. |
| idLabels | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor. |
| grid | an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE. |
| ... | optional arguments passed to the Trellis plot function. |

## Value

a diagnostic Trellis plot for assessing normality of residuals.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

gls, plot.gls

## Examples

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
qqnorm(fm1, abline = c(0,1))
```

qqnorm.lme *Normal Plot of Residuals or Random Effects from an lme Object*

## Description

Diagnostic plots for assessing the normality of residuals and random effects in the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

## Usage

```
## S3 method for class 'lme'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

## Arguments

| | |
|---|---|
| `y` | an object inheriting from class `"lme"`, representing a fitted linear mixed-effects model or from class `"lmList"`, representing a list of `lm` objects, or from class `"lm"`, representing a fitted linear model, or from class `"nls"`, representing a nonlinear least squares fitted model. |
| `form` | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain `y` can be referenced. In addition, `y` itself can be referenced in the formula using the symbol `"."`. Conditional expressions on the right of a `|` operator can be used to define separate panels in a Trellis display. The expression on the right hand side of `form` and to the left of a `|` operator must evaluate to a residuals vector, or a random effects matrix. Default is `~ resid(., type = "p")`, corresponding to a normal plot of the standardized residuals evaluated at the innermost level of nesting. |
| `abline` | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot. |
| `id` | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using `idLabels`. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified. |
| `idLabels` | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to `id`. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor. |
| `grid` | an optional logical value indicating whether a grid should be added to plot. Default is `FALSE`. |
| `...` | optional arguments passed to the Trellis plot function. |

### Value

a diagnostic Trellis plot for assessing normality of residuals or random effects.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

lme, plot.lme

### Examples

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
## normal plot of standardized residuals by gender
qqnorm(fm1, ~ resid(., type = "p") | Sex, abline = c(0, 1))
## normal plots of random effects
qqnorm(fm1, ~ranef(.))
```

---

## Quinidine *Quinidine Kinetics*

---

### Description

The Quinidine data frame has 1471 rows and 14 columns.

### Format

This data frame contains the following columns:

**Subject** a factor identifying the patient on whom the data were collected.

**time** a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.

**conc** a numeric vector giving the serum quinidine concentration (mg/L).

**dose** a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.

**interval** a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.

**Age** a numeric vector giving the age of the subject on entry to the study (yr).

**Height** a numeric vector giving the height of the subject on entry to the study (in.).

**Weight** a numeric vector giving the body weight of the subject (kg).

**Race** a factor with levels Caucasian, Latin, and Black identifying the race of the subject.

**Smoke** a factor with levels no and yes giving smoking status at the time of the measurement.

**Ethanol** a factor with levels none, current, former giving ethanol (alcohol) abuse status at the time of the measurement.

**Heart** a factor with levels No/Mild, Moderate, and Severe indicating congestive heart failure for the subject.

**Creatinine** an ordered factor with levels < 50 < >= 50 indicating the creatine clearance (mg/min).

**glyco** a numeric vector giving the alpha-1 acid glycoprotein concentration (mg/dL). Often measured at the same time as the quinidine concentration.

## Details

Verme et al. (1992) analyze routine clinical data on patients receiving the drug quinidine as a treatment for cardiac arrythmia (atrial fibrillation of ventricular arrythmias). All patients were receiving oral quinidine doses. At irregular intervals blood samples were drawn and serum concentrations of quinidine were determined. These data are analyzed in several publications, including Davidian and Giltinan (1995, section 9.3).

---

`quinModel` *Model function for the Quinidine data*

---

## Description

A model function for a model used with the `Quinidine` data. This function calls compiled C code.

## Usage

```
quinModel(Subject, time, conc, dose, interval, lV, lKa, lCl)
```

## Arguments

| | |
|---|---|
| `Subject` | a factor identifying the patient on whom the data were collected. |
| `time` | a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study. |
| `conc` | a numeric vector giving the serum quinidine concentration (mg/L). |
| `dose` | a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base. |
| `interval` | a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded. |
| `lV` | numeric. A vector of values of the natural log of the effective volume of distribution according to `Subject` and `time`. |
| `lKa` | numeric. A vector of values of the natural log of the absorption rate constant according to `Subject` and `time`. |
| `lCl` | numeric. A vector of values of the natural log of the clearance parameter according to `Subject` and `time`. |

## Details

See the details section of `Quinidine` for a description of the model function that `quinModel` evaluates.

## Value

a numeric vector of predicted quinidine concentrations.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

`Rail` *Evaluation of Stress in Railway Rails*

---

## Description

The `Rail` data frame has 18 rows and 2 columns.

## Format

This data frame contains the following columns:

**Rail** an ordered factor identifying the rail on which the measurement was made.

**travel** a numeric vector giving the travel time for ultrasonic head-waves in the rail (nanoseconds). The value given is the original travel time minus 36,100 nanoseconds.

## Details

Devore (2000, Example 10.10, p. 427) cites data from an article in *Materials Evaluation* on "a study of travel time for a certain type of wave that results from longitudinal stress of rails used for railroad track."

## random.effects — *Extract Random Effects*

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmList` and `lme`.

### Usage

```
random.effects(object, ...)
ranef(object, ...)
```

### Arguments

| | |
|---|---|
| `object` | any fitted model object from which random effects estimates can be extracted. |
| `...` | some methods for this generic function require additional arguments. |

### Value

will depend on the method function used; see the appropriate documentation.

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. pp. 100, 461.

### See Also

`ranef.lmList`,`ranef.lme`

### Examples

```
## see the method function documentation
```

## ranef.lme — *Extract lme Random Effects*

### Description

The estimated random effects at level $i$ are represented as a data frame with rows given by the different groups at that level and columns given by the random effects. If a single level of grouping is specified, the returned object is a data frame; else, the returned object is a list of such data frames. Optionally, the returned data frame(s) may be augmented with covariates summarized over groups.

### Usage

```
## S3 method for class 'lme'
ranef(object, augFrame, level, data, which, FUN,
      standard, omitGroupingFactor, subset, ...)
```

### Arguments

- `object` — an object inheriting from class "`lme`", representing a fitted linear mixed-effects model.
- `augFrame` — an optional logical value. If `TRUE`, the returned data frame is augmented with variables defined in `data`; else, if `FALSE`, only the coefficients are returned. Defaults to `FALSE`.
- `level` — an optional vector of positive integers giving the levels of grouping to be used in extracting the random effects from an object with multiple nested grouping levels. Defaults to all levels of grouping.
- `data` — an optional data frame with the variables to be used for augmenting the returned data frame when `augFrame = TRUE`. Defaults to the data frame used to fit `object`.
- `which` — an optional positive integer vector specifying which columns of `data` should be used in the augmentation of the returned data frame. Defaults to all columns in `data`.
- `FUN` — an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing `data` by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If `FUN` is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If `FUN` is a list of functions, the names in the list should designate classes of variables in the frame such as `ordered`, `factor`, or `numeric`. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are `mean` for numeric factors, and `Mode` for both `factor` and `ordered`. The `Mode` function, defined internally in `gsummary`, returns the modal or most popular value of the variable. It is different from the `mode` function that returns the S-language mode of the variable.
- `standard` — an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the estimate of the standard deviation of that group of random effects). Defaults to `FALSE`.
- `omitGroupingFactor` — an optional logical value. When `TRUE` the grouping factor itself will be omitted from the group-wise summary of `data` but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to `FALSE`.
- `subset` — an optional expression indicating for which rows the random effects should be extracted.
- `...` — some methods for this generic require additional arguments. None are used in this method.

### Value

a data frame, or list of data frames, with the estimated random effects at the grouping level(s) specified in `level` and, optionally, other covariates summarized over groups. The returned object inherits from classes `random.effects.lme` and `data.frame`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. pp. 100, 461.

random.effects(fm1, augFrame = TRUE)
```

---

ranef.lmList *Extract lmList Random Effects*

---

## Description

The difference between the individual lm components coefficients and their average is calculated.

## Usage

```
## S3 method for class 'lmList'
ranef(object, augFrame, data, which, FUN, standard,
                 omitGroupingFactor, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "lmList", representing a list of lm objects with a common model. |
| augFrame | an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE. |
| data | an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object. |
| which | an optional positive integer vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data. |
| FUN | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, |

defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

standard
: an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the corresponding estimated standard error). Defaults to FALSE.

omitGroupingFactor
: an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

...
: some methods for this generic require additional arguments. None are used in this method.

## Value

a vector with the differences between the individual lm coefficients in object and their average.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

RatPupWeight *The weight of rat pups*

---

## Description

The RatPupWeight data frame has 322 rows and 5 columns.

## Format

This data frame contains the following columns:

**weight** a numeric vector

**sex** a factor with levels Male Female

**Litter** an ordered factor with levels 9 < 8 < 7 < 4 < 2 < 10 < 1 < 3 < 5 < 6 < 21 < 22 < 24 < 27 < 26 < 25 < 23 < 17 < 11 < 14 < 13 < 15 < 16 < 20 < 19 < 18 < 12

**Lsize** a numeric vector

**Treatment** an ordered factor with levels Control < Low < High

---

`recalc` *Recalculate Condensed Linear Model Object*

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, `modelStruct`, `reStruct`, and `varFunc`.

## Usage

```
recalc(object, conLin, ...)
```

## Arguments

| | |
|---|---|
| `object` | any object which induces a recalculation of the condensed linear model object `conLin`. |
| `conLin` | a condensed linear model object, consisting of a list with components `"Xy"`, corresponding to a regression matrix (`X`) combined with a response vector (`y`), and `"logLik"`, corresponding to the log-likelihood of the underlying model. |
| `...` | some methods for this generic can take additional arguments. |

## Value

the recalculated condensed linear model object.

## Note

This function is only used inside model fitting functions, such as `lme` and `gls`, that require recalculation of a condensed linear model object.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

`recalc.corStruct`, `recalc.modelStruct`, `recalc.reStruct`, `recalc.varFunc`

## Examples

```
## see the method function documentation
```

## recalc.corStruct *Recalculate for corStruct Object*

### Description

This method function pre-multiples the "Xy" component of conLin by the transpose square-root factor(s) of the correlation matrix (matrices) associated with object and adds the log-likelihood contribution of object, given by logLik(object), to the "logLik" component of conLin.

### Usage

```
## S3 method for class 'corStruct'
recalc(object, conLin, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "corStruct", representing a correlation structure. |
| conLin | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

the recalculated condensed linear model object.

### Note

This method function is only used inside model fitting functions, such as lme and gls, that allow correlated error terms.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

corFactor, logLik.corStruct

## recalc.modelStruct *Recalculate for a modelStruct Object*

### Description

This method function recalculates the condensed linear model object using each element of `object` sequentially from last to first.

### Usage

```
## S3 method for class 'modelStruct'
recalc(object, conLin, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"modelStruct"`, representing a list of model components, such as `corStruct` and `varFunc` objects. |
| `conLin` | an optional condensed linear model object, consisting of a list with components `"Xy"`, corresponding to a regression matrix (`X`) combined with a response vector (`y`), and `"logLik"`, corresponding to the log-likelihood of the underlying model. Defaults to `attr(object, "conLin")`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

the recalculated condensed linear model object.

### Note

This method function is generally only used inside model fitting functions, such as `lme` and `gls`, that allow model components, such as correlated error terms and variance functions.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`recalc.corStruct`, `recalc.reStruct`, `recalc.varFunc`

## recalc.reStruct — *Recalculate for an reStruct Object*

### Description

The log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)` is calculated and added to the `logLik` component of `conLin`. The `settings` attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods for the (restricted) log-likelihood calculations are described in Bates and Pinheiro (1998).

### Usage

```
## S3 method for class 'reStruct'
recalc(object, conLin, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"reStruct"`, representing a random effects structure and consisting of a list of `pdMat` objects. |
| `conLin` | a condensed linear model object, consisting of a list with components `"Xy"`, corresponding to a regression matrix (`X`) combined with a response vector (`y`), and `"logLik"`, corresponding to the log-likelihood of the underlying model. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

the condensed linear model with its `logLik` component updated.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`logLik`, `lme`, `recalc`, `reStruct`

## recalc.varFunc — *Recalculate for varFunc Object*

### Description

This method function pre-multiples the `"Xy"` component of `conLin` by a diagonal matrix with diagonal elements given by the weights corresponding to the variance structure represented by `objecte` and adds the log-likelihood contribution of `object`, given by `logLik(object)`, to the `"logLik"` component of `conLin`.

### Usage

```
## S3 method for class 'varFunc'
recalc(object, conLin, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`varFunc`", representing a variance function structure. |
| `conLin` | a condensed linear model object, consisting of a list with components "`Xy`", corresponding to a regression matrix (`X`) combined with a response vector (`y`), and "`logLik`", corresponding to the log-likelihood of the underlying model. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

the recalculated condensed linear model object.

### Note

This method function is only used inside model fitting functions, such as `lme` and `gls`, that allow heteroscedastic error terms.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`recalc`, `varWeights`, `logLik.varFunc`

---

## `Relaxin` *Assay for Relaxin*

---

### Description

The `Relaxin` data frame has 198 rows and 3 columns.

### Format

This data frame contains the following columns:

**Run** an ordered factor with levels 5 < 8 < 9 < 3 < 4 < 2 < 7 < 1 < 6

**conc** a numeric vector

**cAMP** a numeric vector

### Source

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

## Remifentanil — *Pharmacokinetics of remifentanil*

### Description

The `Remifentanil` data frame has 2107 rows and 12 columns.

### Format

This data frame contains the following columns:

**ID** a numeric vector

**Subject** an ordered factor

**Time** a numeric vector

**conc** a numeric vector

**Rate** a numeric vector

**Amt** a numeric vector

**Age** a numeric vector

**Sex** a factor with levels `Female` `Male`

**Ht** a numeric vector

**Wt** a numeric vector

**BSA** a numeric vector

**LBM** a numeric vector

### Source

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

## residuals.gls — *Extract gls Residuals*

### Description

The residuals for the linear model represented by `object` are extracted.

### Usage

```
## S3 method for class 'gls'
residuals(object, type, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`gls`", representing a generalized least squares fitted linear model, or from class `gnls`, representing a generalized nonlinear least squares fitted linear model. |
| `type` | an optional character string specifying the type of residuals to be used. If "`response`", the "raw" residuals (observed - fitted) are used; else, if "`pearson`", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "`normalized`", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "`response`". |
| `...` | some methods for this generic function require additional arguments. None are used in this method. |

### Value

a vector with the residuals for the linear model represented by `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`gls`

### Examples

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
residuals(fm1)
```

---

## `residuals.glsStruct` *Calculate glsStruct Residuals*

---

### Description

The residuals for the linear model represented by `object` are extracted.

### Usage

```
## S3 method for class 'glsStruct'
residuals(object, glsFit, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`glsStruct`", representing a list of linear model components, such as `corStruct` and "`varFunc`" objects. |
| `glsFit` | an optional list with components `logLik` (log-likelihood), `beta` (coefficients), `sigma` (standard deviation for error term), `varBeta` (coefficients' covariance matrix), `fitted` (fitted values), and `residuals` (residuals). Defaults to `attr(object, "glsFit")`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

a vector with the residuals for the linear model represented by `object`.

### Note

This method function is primarily used inside `gls` and `residuals.gls`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`gls`, `glsStruct`, `residuals.gls`, `fitted.glsStruct`

---

## `residuals.gnlsStruct` *Calculate gnlsStruct Residuals*

---

### Description

The residuals for the nonlinear model represented by `object` are extracted.

### Usage

```
## S3 method for class 'gnlsStruct'
residuals(object, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`gnlsStruct`", representing a list of model components, such as `corStruct` and `varFunc` objects, and attributes specifying the underlying nonlinear model and the response variable. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

a vector with the residuals for the nonlinear model represented by `object`.

## Note

This method function is primarily used inside gnls and residuals.gnls.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

gnls, residuals.gnls, fitted.gnlsStruct

---

residuals.lme *Extract lme Residuals*

---

## Description

The residuals at level $i$ are obtained by subtracting the fitted levels at that level from the response vector (and dividing by the estimated within-group standard error, if type="pearson"). The fitted values at level $i$ are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to $i$.

## Usage

```
## S3 method for class 'lme'
residuals(object, level = Q,
          type = c("response", "pearson", "normalized"), asList = FALSE, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "lme", representing a fitted linear mixed-effects model. |
| level | an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population residuals. Defaults to the highest or innermost level of grouping. |
| type | an optional character string specifying the type of residuals to be used. If "response", as by default, the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. |
| asList | an optional logical value. If TRUE and a single value is given in level, the returned object is a list with the residuals split by groups; else the returned value is either a vector or a data frame, according to the length of level. Defaults to FALSE. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

if a single level of grouping is specified in `level`, the returned value is either a list with the residuals split by groups (`asList = TRUE`) or a vector with the residuals (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the residuals at different levels and the grouping factors. For a vector or data frame result the `naresid` method is applied.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lme`, `fitted.lme`

### Examples

```
fm1 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
head(residuals(fm1, level = 0:1))
summary(residuals(fm1) /
        residuals(fm1, type = "p")) # constant scaling factor 1.432
```

---

## residuals.lmeStruct *Calculate lmeStruct Residuals*

---

### Description

The residuals at level $i$ are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level $i$ are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to $i$.

### Usage

```
## S3 method for class 'lmeStruct'
residuals(object, level, conLin, lmeFit, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`lmeStruct`", representing a list of linear mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects. |
| `level` | an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping. |
| `conLin` | an optional condensed linear model object, consisting of a list with components "`Xy`", corresponding to a regression matrix (`X`) combined with a response vector (`y`), and "`logLik`", corresponding to the log-likelihood of the underlying lme model. Defaults to `attr(object, "conLin")`. |
| `lmeFit` | an optional list with components `beta` and `b` containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the residuals. Defaults to `attr(object, "lmeFit")`. |
| `...` | some methods for this generic accept optional arguments. |

### Value

if a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

### Note

This method function is primarily used within the `lme` function.

## residuals.lmList *Extract lmList Residuals*

---

### Description

The residuals are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

### Usage

```
## S3 method for class 'lmList'
residuals(object, type, subset, asList, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"lmList"`, representing a list of `lm` objects with a common model. |
| `subset` | an optional character or integer vector naming the `lm` components of `object` from which the residuals are to be extracted. Default is `NULL`, in which case all components are used. |
| `type` | an optional character string specifying the type of residuals to be extracted. Options include `"response"` for the "raw" residuals (observed - fitted), `"pearson"` for the standardized residuals (raw residuals divided by the estimated residual standard error) using different standard errors for each `lm` fit, and `"pooled.pearson"` for the standardized residuals using a pooled estimate of the residual standard error. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to `"response"`. |
| `asList` | an optional logical value. If `TRUE`, the returned object is a list with the residuals split by groups; else the returned value is a vector. Defaults to `FALSE`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

a list with components given by the residuals of each `lm` component of `object`, or a vector with the residuals for all `lm` components of `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lmList`, `fitted.lmList`

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
residuals(fm1)
```

---

## residuals.nlmeStruct *Calculate nlmeStruct Residuals*

---

### Description

The residuals at level $i$ are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level $i$ are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to $i$ and evaluating the model function at the resulting estimated parameters.

### Usage

```
## S3 method for class 'nlmeStruct'
residuals(object, level, conLin, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"nlmeStruct"`, representing a list of mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects. |
| `level` | an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping. |
| `conLin` | an optional condensed linear model object, consisting of a list with components `"Xy"`, corresponding to a regression matrix (`X`) combined with a response vector (`y`), and `"logLik"`, corresponding to the log-likelihood of the underlying nlme model. Defaults to `attr(object, "conLin")`. |
| `...` | optional arguments to the residuals generic. Not used. |

### Value

if a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

## Note

This method function is primarily used within the `nlme` function.

`reStruct` *Random Effects Structure*

---

## Description

This function is a constructor for the `reStruct` class, representing a random effects structure and consisting of a list of `pdMat` objects, plus a `settings` attribute containing information for the optimization algorithm used to fit the associated mixed-effects model.

## Usage

```
reStruct(object, pdClass, REML, data)
## S3 method for class 'reStruct'
print(x, sigma, reEstimates, verbose, ...)
```

## Arguments

`object` any of the following: (i) a one-sided formula of the form `~x1+...+xn | g1/.../gm`, with `x1+...+xn` specifying the model for the random effects and `g1/.../gm` the grouping structure (`m` may be equal to 1, in which case no `/` is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form `~x1+...+xn | g`, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form `~x1+...+xn`, or a `pdMat` object with a formula (i.e. a non-`NULL` value for `formula(object)`), or a list of such formulas or `pdMat` objects. In this case, the grouping structure formula will be derived from the data used to to fit the mixed-effects model, which should inherit from class `groupedData`; (iv) a named list of formulas or `pdMat` objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (v) an `reStruct` object.

`pdClass` an optional character string with the name of the `pdMat` class to be used for the formulas in `object`. Defaults to `"pdSymm"` which corresponds to a general positive-definite matrix.

| | |
|---|---|
| REML | an optional logical value. If TRUE, the associated mixed-effects model will be fitted using restricted maximum likelihood; else, if FALSE, maximum likelihood will be used. Defaults to FALSE. |
| data | an optional data frame in which to evaluate the variables used in the random effects formulas in object. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying pdMat objects. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| x | an object inheriting from class reStruct to be printed. |
| sigma | an optional numeric value used as a multiplier for the square-root factors of the pdMat components (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1. |
| reEstimates | an optional list with the random effects estimates for each level of grouping. Only used when verbose = TRUE. |
| verbose | an optional logical value determining if the random effects estimates should be printed. Defaults to FALSE. |
| ... | Optional arguments can be given to other methods for this generic. None are used in this method. |

## Value

an object inheriting from class reStruct, representing a random effects structure.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

groupedData, lme, pdMat, solve.reStruct, summary.reStruct, update.reStruct

## Examples

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
rs1
```

---

simulate.lme *Simulate Results from* lme *Models*

---

## Description

The model object is fit to the data. Using the fitted values of the parameters, nsim new data vectors from this model are simulated. Both object and m2 are fit by maximum likelihood (ML) and/or by restricted maximum likelihood (REML) to each of the simulated data vectors.

## Usage

```
## S3 method for class 'lme'
simulate(object, nsim = 1, seed = , m2,
         method = c("REML", "ML"), niterEM = c(40, 200), useGen, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "lme", representing a fitted linear mixed-effects model, or a list containing an lme model specification. If given as a list, it should contain components fixed, data, and random with values suitable for a call to lme. This argument defines the null model. |
| m2 | an "lme" object or a list, like object containing a second lme model specification. This argument defines the alternative model. If given as a list, only those parts of the specification that change between model object and m2 need to be specified. |
| seed | an optional integer that is passed to set.seed. Defaults to a random integer. |
| method | an optional character array. If it includes "REML" the models are fit by maximizing the restricted log-likelihood. If it includes "ML" the log-likelihood is maximized. Defaults to c("REML", "ML"), in which case both methods are used. |
| nsim | an optional positive integer specifying the number of simulations to perform. Defaults to 1. **This has changed. Previously the default was 1000.** |
| niterEM | an optional integer vector of length 2 giving the number of iterations of the EM algorithm to apply when fitting the object and m2 to each simulated set of data. Defaults to c(40,200). |
| useGen | an optional logical value. If TRUE, numerical derivatives are used to obtain the gradient and the Hessian of the log-likelihood in the optimization algorithm in the ms function. If FALSE, the default algorithm in ms for functions that do not incorporate gradient and Hessian attributes is used. Default depends on the "pdMat" classes used in object and m2: if both are standard classes (see pdClasses) then defaults to TRUE, otherwise defaults to FALSE. |
| ... | optional additional arguments. None are used. |

## Value

an object of class simulate.lme with components null and alt. Each of these has components ML and/or REML which are matrices. An attribute called Random.seed contains the seed that was used for the random number generator.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

## Examples

```
orthSim <-
   simulate.lme(list(fixed = distance ~ age, data = Orthodont,
                     random = ~ 1 | Subject), nsim = 200,
                m2 = list(random = ~ age | Subject))
```

## solve.pdMat — *Calculate Inverse of a Positive-Definite Matrix*

### Description

The positive-definite matrix represented by a is inverted and assigned to a.

### Usage

```
## S3 method for class 'pdMat'
solve(a, b, ...)
```

### Arguments

| | |
|---|---|
| a | an object inheriting from class "pdMat", representing a positive definite matrix. |
| b | this argument is only included for consistency with the generic function and is not used in this method function. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

a pdMat object similar to a, but with coefficients corresponding to the inverse of the positive-definite matrix represented by a.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

pdMat

### Examples

```
pd1 <- pdCompSymm(3 * diag(3) + 1)
solve(pd1)
```

## solve.reStruct — *Apply Solve to an reStruct Object*

### Description

Solve is applied to each pdMat component of a, which results in inverting the positive-definite matrices they represent.

### Usage

```
## S3 method for class 'reStruct'
solve(a, b, ...)
```

### Arguments

| | |
|---|---|
| a | an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects. |
| b | this argument is only included for consistency with the generic function and is not used in this method function. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

an reStruct object similar to a, but with the pdMat components representing the inverses of the matrices represented by the components of a.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

solve.pdMat, reStruct

### Examples

```
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
  B = pdDiag(2 * diag(4), form = ~Educ)))
solve(rs1)
```

---

## Soybean *Growth of soybean plants*

---

### Description

The Soybean data frame has 412 rows and 5 columns.

### Format

This data frame contains the following columns:

**Plot** a factor giving a unique identifier for each plot.

**Variety** a factor indicating the variety; Forrest (F) or Plant Introduction \#416937 (P).

**Year** a factor indicating the year the plot was planted.

**Time** a numeric vector giving the time the sample was taken (days after planting).

**weight** a numeric vector giving the average leaf weight per plant (g).

### Details

These data are described in Davidian and Giltinan (1995, 1.1.3, p.7) as "Data from an experiment to compare growth patterns of two genotypes of soybeans: Plant Introduction \#416937 (P), an experimental strain, and Forrest (F), a commercial variety."

### Source

### Examples

```
summary(fm1 <- nlsList(SSlogis, data = Soybean))
```

---

## splitFormula *Split a Formula*

---

### Description

Splits the right hand side of `form` into a list of subformulas according to the presence of `sep`. The left hand side of `form`, if present, will be ignored. The length of the returned list will be equal to the number of occurrences of `sep` in `form` plus one.

### Usage

```
splitFormula(form, sep)
```

### Arguments

| | |
|---|---|
| `form` | a `formula` object. |
| `sep` | an optional character string specifying the separator to be used for splitting the formula. Defaults to `"/"`. |

### Value

a list of formulas, corresponding to the split of `form` according to `sep`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`formula`

### Examples

```
splitFormula(~ g1/g2/g3)
```

## Spruce — *Growth of Spruce Trees*

### Description

The Spruce data frame has 1027 rows and 4 columns.

### Format

This data frame contains the following columns:

**Tree** a factor giving a unique identifier for each tree.

**days** a numeric vector giving the number of days since the beginning of the experiment.

**logSize** a numeric vector giving the logarithm of an estimate of the volume of the tree trunk.

**plot** a factor identifying the plot in which the tree was grown.

### Details

Diggle, Liang, and Zeger (1994, Example 1.3, page 5) describe data on the growth of spruce trees that have been exposed to an ozone-rich atmosphere or to a normal atmosphere.

## summary.corStruct — *Summarize a corStruct Object*

### Description

This method function prepares object to be printed using the print.summary method, by changing its class and adding a structName attribute to it.

### Usage

```
## S3 method for class 'corStruct'
summary(object, structName, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "corStruct", representing a correlation structure. |
| structName | an optional character string defining the type of correlation structure associated with object, to be used in the print.summary method. Defaults to class(object)[1]. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

an object identical to `object`, but with its class changed to `summary.corStruct` and an additional attribute `structName`. The returned value inherits from the same classes as `object`.

### Author(s)

José Pinheiro and Douglas Bates

### See Also

`corClasses`, `corNatural`, `Initialize.corStruct`, `summary`

### Examples

```
cs1 <- corAR1(0.2)
summary(cs1)
```

---

## summary.gls — *Summarize a Generalized Least Squares* `gls` *Object*

---

### Description

Additional information about the linear model fit represented by `object` is extracted and included as components of `object`.

### Usage

```
## S3 method for class 'gls'
summary(object, verbose, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`gls`", representing a generalized least squares fitted linear model. |
| `verbose` | an optional logical value used to control the amount of output when the object is printed. Defaults to `FALSE`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

an object inheriting from class `summary.gls` with all components included in `object` (see `glsObject` for a full description of the components) plus the following components:

| | |
|---|---|
| `corBeta` | approximate correlation matrix for the coefficients estimates |
| `tTable` | a matrix with columns `Value`, `Std. Error`, `t-value`, and `p-value` representing respectively the coefficients estimates, their approximate standard errors, the ratios between the estimates and their standard errors, and the associated p-value under a $t$ approximation. Rows correspond to the different coefficients. |

| | |
|---|---|
| residuals | if more than five observations are used in the gls fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the residuals distribution; else the residuals. |
| AIC | the Akaike Information Criterion corresponding to object. |
| BIC | the Bayesian Information Criterion corresponding to object. |

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

AIC, BIC, gls, summary

## Examples

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
summary(fm1)
coef(summary(fm1)) # "the matrix"
```

---

summary.lme *Summarize an lme Object*

---

## Description

Additional information about the linear mixed-effects fit represented by object is extracted and included as components of object. The returned object has a print and a coef method, the latter returning the coefficient's tTtable.

## Usage

```
## S3 method for class 'lme'
summary(object, adjustSigma, verbose, ...)
## S3 method for class 'summary.lme'
print(x, verbose = FALSE, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "lme", representing a fitted linear mixed-effects model. |
| adjustSigma | an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$, converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE. |
| verbose | an optional logical value used to control the amount of output in the print.summary.lme method. Defaults to FALSE. |
| ... | additional optional arguments passed to methods, mainly for the print method. |
| x | a "summary.lme" object. ! |

### Value

an object inheriting from class `summary.lme` with all components included in `object` (see `lmeObject` for a full description of the components) plus the following components:

| | |
|---|---|
| `corFixed` | approximate correlation matrix for the fixed effects estimates. |
| `tTable` | a matrix with columns named `Value`, `Std. Error`, `DF`, `t-value`, and `p-value` representing respectively the fixed effects estimates, their approximate standard errors, the denominator degrees of freedom, the ratios between the estimates and their standard errors, and the associated p-value from a t distribution. Rows correspond to the different fixed effects. |
| `residuals` | if more than five observations are used in the `lme` fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the innermost grouping level residuals distribution; else the innermost grouping level residuals. |
| `AIC` | the Akaike Information Criterion corresponding to `object`. |
| `BIC` | the Bayesian Information Criterion corresponding to `object`. |

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`AIC`, `BIC`, `lme`.

### Examples

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
(s1 <- summary(fm1))
## Not run: coef(s1) # the (coef | Std.E | t | P-v ) matrix
```

---

## `summary.lmList` *Summarize an lmList Object*

---

### Description

The `summary.lm` method is applied to each `lm` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.lmList` method.

### Usage

```
## S3 method for class 'lmList'
summary(object, pool, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"lmList"`, representing a list of `lm` fitted objects. |
| `pool` | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is `attr(object, "pool")`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

a list with summary statistics obtained by applying `summary.lm` to the elements of `object`, inheriting from class `summary.lmList`. The components of `value` are:

- `call` — a list containing an image of the `lmList` call that produced `object`.
- `coefficients` — a three dimensional array with summary information on the `lm` coefficients. The first dimension corresponds to the names of the `object` components, the second dimension is given by `"Value"`, `"Std. Error"`, `"t value"`, and `"Pr(>|t|)"`, corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.
- `correlation` — a three dimensional array with the correlations between the individual `lm` coefficient estimates. The first dimension corresponds to the names of the `object` components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by `lm` component.
- `cov.unscaled` — a three dimensional array with the unscaled variances/covariances for the individual `lm` coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the `object` components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by `lm` component.
- `df` — an array with the number of degrees of freedom for the model and for residuals, for each `lm` component.
- `df.residual` — the total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all `lm` components.
- `fstatistics` — an array with the F test statistics and corresponding degrees of freedom, for each `lm` component.
- `pool` — the value of the `pool` argument to the function.
- `r.squared` — a vector with the multiple R-squared statistics for each `lm` component.
- `residuals` — a list with components given by the residuals from individual `lm` fits.
- `RSE` — the pooled estimate of the residual standard error.
- `sigma` — a vector with the residual standard error estimates for the individual `lm` fits.
- `terms` — the terms object used in fitting the individual `lm` components.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

`lmList`, `summary`

## Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
summary(fm1)
```

## summary.modelStruct *Summarize a modelStruct Object*

### Description

This method function applies summary to each element of object.

### Usage

```
## S3 method for class 'modelStruct'
summary(object, ...)
```

### Arguments

| | |
|---|---|
| object | an object inheriting from class "modelStruct", representing a list of model components, such as reStruct, corStruct and varFunc objects. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

### Value

a list with elements given by the summarized components of object. The returned value is of class summary.modelStruct, also inheriting from the same classes as object.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

reStruct, summary

### Examples

```
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
   corStruct = corAR1(0.3))
summary(lms1)
```

## summary.nlsList *Summarize an nlsList Object*

### Description

The summary function is applied to each nls component of object to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the print.summary.nlsList method.

### Usage

```
## S3 method for class 'nlsList'
summary(object, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "nlsList", representing a list of nls fitted objects. |
| ... | optional arguments to the summary.lmList method. One such optional argument is pool, a logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object, "pool"). |

## Value

a list with summary statistics obtained by applying summary to the elements of object, inheriting from class summary.nlsList. The components of value are:

| | |
|---|---|
| call | a list containing an image of the nlsList call that produced object. |
| parameters | a three dimensional array with summary information on the nls coefficients. The first dimension corresponds to the names of the object components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(>\|t\|)", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names. |
| correlation | a three dimensional array with the correlations between the individual nls coefficient estimates. The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by nls component. |
| cov.unscaled | a three dimensional array with the unscaled variances/covariances for the individual lm coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by nls component. |
| df | an array with the number of degrees of freedom for the model and for residuals, for each nls component. |
| df.residual | the total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all nls components. |
| pool | the value of the pool argument to the function. |
| RSE | the pooled estimate of the residual standard error. |
| sigma | a vector with the residual standard error estimates for the individual lm fits. |

## Author(s)

## Examples

```
fm1 <- nlsList(SSasymp, Loblolly)
summary(fm1)
```

summary.pdMat *Summarize a pdMat Object*

## Description

Attributes structName and noCorrelation, with the values of the corresponding arguments to the method function, are appended to object and its class is changed to summary.pdMat.

## Usage

```
## S3 method for class 'pdMat'
summary(object, structName, noCorrelation, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "pdMat", representing a positive definite matrix. |
| structName | an optional character string with a description of the pdMat class. Default depends on the method function: "Blocked" for pdBlocked, "Compound Symmetry" for pdCompSymm, "Diagonal" for pdDiag, "Multiple of an Identity" for pdIdent, "General Positive-Definite, Natural Parametrization" for pdNatural, "General Positive-Definite" for pdSymm, and data.class(object) for pdMat. |
| noCorrelation | an optional logical value indicating whether correlations are to be printed in print.summary.pdMat. Default depends on the method function: FALSE for pdDiag and pdIdent, and TRUE for all other classes. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

## Value

an object similar to object, with additional attributes structName and noCorrelation, inheriting from class summary.pdMat.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

print.summary.pdMat, pdMat

## Examples

```
summary(pdSymm(diag(4)))
```

summary.varFunc *Summarize varFunc Object*

## Description

A structName attribute, with the value of corresponding argument, is appended to object and its class is changed to summary.varFunc.

## Usage

```
## S3 method for class 'varFunc'
summary(object, structName, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "varFunc", representing a variance function structure. |
| structName | an optional character string with a description of the varFunc class. Default depends on the method function: "Combination of variance functions" for varComb, "Constant plus power of covariate" for varConstPower, "Exponential of variance covariate" for varExp, "Different standard deviations per stratum" for varIdent, "Power of variance covariate" for varPower, and data.class(object) for varFunc. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

## Value

an object similar to object, with an additional attribute structName, inheriting from class summary.varFunc.

## Tetracycline1 *Pharmacokinetics of tetracycline*

### Description

The `Tetracycline1` data frame has 40 rows and 4 columns.

### Format

This data frame contains the following columns:

**conc** a numeric vector

**Time** a numeric vector

**Subject** an ordered factor with levels `5 < 3 < 2 < 4 < 1`

**Formulation** a factor with levels `tetrachel` `tetracyn`

### Source

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

## Tetracycline2 *Pharmacokinetics of tetracycline*

### Description

The `Tetracycline2` data frame has 40 rows and 4 columns.

### Format

This data frame contains the following columns:

**conc** a numeric vector

**Time** a numeric vector

**Subject** an ordered factor with levels `4 < 5 < 2 < 1 < 3`

**Formulation** a factor with levels `Berkmycin` `tetramycin`

### Source

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

## update.modelStruct *Update a modelStruct Object*

### Description

This method function updates each element of `object`, allowing the access to `data`.

### Usage

```
## S3 method for class 'modelStruct'
update(object, data, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"modelStruct"`, representing a list of model components, such as `corStruct` and `varFunc` objects. |
| `data` | a data frame in which to evaluate the variables needed for updating the elements of `object`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

an object similar to `object` (same class, length, and names), but with updated elements.

### Note

This method function is primarily used within model fitting functions, such as `lme` and `gls`, that allow model components such as variance functions.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`reStruct`

## update.varFunc *Update varFunc Object*

### Description

If the `formula(object)` includes a `"."` term, representing a fitted object, the variance covariate needs to be updated upon completion of an optimization cycle (in which the variance function weights are kept fixed). This method function allows a reevaluation of the variance covariate using the current fitted object and, optionally, other variables in the original data.

### Usage

```
## S3 method for class 'varFunc'
update(object, data, ...)
```

### Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`varFunc`", representing a variance function structure. |
| `data` | a list with a component named "`.`" with the current version of the fitted object (from which fitted values, coefficients, and residuals can be extracted) and, if necessary, other variables used to evaluate the variance covariate(s). |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

if `formula(object)` includes a "`.`" term, an `varFunc` object similar to `object`, but with the variance covariate reevaluated at the current fitted object value; else `object` is returned unchanged.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

`needUpdate`, `covariate<-.varFunc`

---

## varClasses *Variance Function Classes*

---

### Description

Standard classes of variance function structures (`varFunc`) available in the `nlme` package. Covariates included in the variance function, denoted by variance covariates, may involve functions of the fitted model object, such as the fitted values and the residuals. Different coefficients may be assigned to the levels of a classification factor.

### Value

Available standard classes:

| | |
|---|---|
| `varExp` | exponential of a variance covariate. |
| `varPower` | power of a variance covariate. |
| `varConstPower` | constant plus power of a variance covariate. |
| `varIdent` | constant variance(s), generally used to allow different variances according to the levels of a classification factor. |
| `varFixed` | fixed weights, determined by a variance covariate. |
| `varComb` | combination of variance functions. |

## Note

Users may define their own varFunc classes by specifying a constructor function and, at a minimum, methods for the functions coef, coef<-, and initialize. For examples of these functions, see the methods for class varPower.

---

varComb *Combination of Variance Functions*

---

## Description

This function is a constructor for the varComb class, representing a combination of variance functions. The corresponding variance function is equal to the product of the variance functions of the varFunc objects listed in ....

## Usage

```
varComb(...)
```

## Arguments

| | |
|---|---|
| ... | objects inheriting from class varFunc representing variance function structures. |

## Value

a varComb object representing a combination of variance functions, also inheriting from class varFunc.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

## See Also

varClasses, varWeights.varComb, coef.varComb

## Examples

```
vf1 <- varComb(varIdent(form = ~1|Sex), varPower())
```

varConstPower *Constant Plus Power Variance Function*

## Description

This function is a constructor for the varConstPower class, representing a constant plus power variance function structure. Letting $v$ denote the variance covariate and $\sigma^2(v)$ denote the variance function evaluated at $v$, the constant plus power variance function is defined as $\sigma^2(v) = (\theta_1 + |v|_2^{\theta})^2$, where $\theta_1, \theta_2$ are the variance function coefficients. When a grouping factor is present, different $\theta_1, \theta_2$ are used for each factor level.

## Usage

```
varConstPower(const, power, form, fixed)
```

## Arguments

| | |
|---|---|
| const, power | optional numeric vectors, or lists of numeric values, with, respectively, the coefficients for the constant and the power terms. Both arguments must have length one, unless a grouping factor is specified in form. If either argument has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in form. If a grouping factor is present in form and the argument has length one, its value will be assigned to all grouping levels. Only positive values are allowed for const. Default is numeric(0), which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one). |
| form | an optional one-sided formula of the form ~ v, or ~ v \| g, specifying a variance covariate v and, optionally, a grouping factor g for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ".", representing a fitted model object from which fitted values (fitted(.)) and residuals (resid(.)) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in form, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the * operator, as in ~ v \| g1 * g2 * g3. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to ~ fitted(.) representing a variance covariate given by the fitted values of a fitted model object and no grouping factor. |
| fixed | an optional list with components const and/or power, consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in form, the components of fixed must have names identifying which coefficients are to be fixed. Coefficients included in fixed are not allowed to vary during the optimization of an objective function. Defaults to NULL, corresponding to no fixed coefficients. |

## Value

a varConstPower object representing a constant plus power variance function structure, also inheriting from class varFunc.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

vf1 <- varConstPower(1.2, 0.2, form = ~age|Sex)
```

---

## VarCorr *Extract variance and correlation components*

---

### Description

This function calculates the estimated variances, standard deviations, and correlations between the random-effects terms in a linear mixed-effects model, of class "lme", or a nonlinear mixed-effects model, of class "nlme". The within-group error variance and standard deviation are also calculated.

### Usage

```
VarCorr(x, sigma = 1, ...)
## S3 method for class 'lme'
VarCorr(x, sigma = x$sigma, rdig = 3, ...)

## S3 method for class 'pdMat'
VarCorr(x, sigma = 1, rdig = 3, ...)
## S3 method for class 'pdBlocked'
VarCorr(x, sigma = 1, rdig = 3, ...)
```

### Arguments

| | |
|---|---|
| x | a fitted model object, usually an object inheriting from class "lme". |
| sigma | an optional numeric value used as a multiplier for the standard deviations. The default is x$sigma or 1 depending on class(x). |
| rdig | an optional integer value specifying the number of digits used to represent correlation estimates. Default is 3. |
| ... | further optional arguments passed to other methods (none for the methods documented here). |

### Value

a matrix with the estimated variances, standard deviations, and correlations for the random effects. The first two columns, named Variance and StdDev, give, respectively, the variance and the standard deviations. If there are correlation components in the random effects model, the third column, named Corr, and the remaining unnamed columns give the estimated correlations among random effects within the same level of grouping. The within-group error variance and standard deviation are included as the last row in the matrix.

### Examples

```
fm1 <- lme(distance ~ age, data = Orthodont, random = ~age)
VarCorr(fm1)
```

---

## varExp — *Exponential Variance Function*

---

### Description

This function is a constructor for the varExp class, representing an exponential variance function structure. Letting $v$ denote the variance covariate and $\sigma^2(v)$ denote the variance function evaluated at $v$, the exponential variance function is defined as $\sigma^2(v) = \exp(2\theta v)$, where $\theta$ is the variance function coefficient. When a grouping factor is present, a different $\theta$ is used for each factor level.

### Usage

```
varExp(value, form, fixed)
```

### Arguments

| | |
|---|---|
| value | an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in form. If value has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in form. If a grouping factor is present in form and value has length one, its value will be assigned to all grouping levels. Default is numeric(0), which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one). |
| form | an optional one-sided formula of the form ~ v, or ~ v \| g, specifying a variance covariate v and, optionally, a grouping factor g for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ".", representing a fitted model object from which fitted values (fitted(.)) and residuals (resid(.)) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in form, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the * operator, like in ~ v \| g1 * g2 * g3. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group |

the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

`fixed` an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

## Value

a `varExp` object representing an exponential variance function structure, also inheriting from class `varFunc`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

## Examples

```
vf1 <- varExp(0.2, form = ~age|Sex)
```

---

# varFixed *Fixed Variance Function*

---

## Description

This function is a constructor for the `varFixed` class, representing a variance function with fixed variances. Letting $v$ denote the variance covariate defined in `value`, the variance function $\sigma^2(v)$ for this class is $\sigma^2(v) = |v|$. The variance covariate $v$ is evaluated once at initialization and remains fixed thereafter. No coefficients are required to represent this variance function.

## Usage

```
varFixed(value)
```

## Arguments

`value` a one-sided formula of the form `~ v` specifying a variance covariate `v`. Grouping factors are ignored.

## Value

a `varFixed` object representing a fixed variance function structure, also inheriting from class `varFunc`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

vf1 <- varFixed(~age)
```

---

## varFunc *Variance Function Structure*

---

### Description

If object is a one-sided formula, it is used as the argument to varFixed and the resulting object is returned. Else, if object inherits from class varFunc, it is returned unchanged.

### Usage

```
varFunc(object)
```

### Arguments

| | |
|---|---|
| object | either an one-sided formula specifying a variance covariate, or an object inheriting from class varFunc, representing a variance function structure. |

### Value

an object from class varFunc, representing a variance function structure.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

summary.varFunc, varFixed, varWeights.varFunc, coef.varFunc

### Examples

```
vf1 <- varFunc(~age)
```

varIdent *Constant Variance Function*

## Description

This function is a constructor for the varIdent class, representing a constant variance function structure. If no grouping factor is present in form, the variance function is constant and equal to one, and no coefficients required to represent it. When form includes a grouping factor with $M > 1$ levels, the variance function allows M different variances, one for each level of the factor. For identifiability reasons, the coefficients of the variance function represent the ratios between the variances and a reference variance (corresponding to a reference group level). Therefore, only $M - 1$ coefficients are needed to represent the variance function. By default, if the elements in value are unnamed, the first group level is taken as the reference level.

## Usage

```
varIdent(value, form, fixed)
```

## Arguments

value — an optional numeric vector, or list of numeric values, with the variance function coefficients. If no grouping factor is present in form, this argument is ignored, as the resulting variance function contains no coefficients. If value has length one, its value is repeated for all coefficients in the variance function. If value has length greater than one, it must have length equal to the number of grouping levels minus one and names which identify its elements to the levels of the grouping factor. Only positive values are allowed for this argument. Default is numeric(0), which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

form — an optional one-sided formula of the form ~ v, or ~ v | g, specifying a variance covariate v and, optionally, a grouping factor g for the coefficients. The variance covariate is ignored in this variance function. When a grouping factor is present in form, a different coefficient value is used for each of its levels less one reference level (see description section below). Several grouping variables may be simultaneously specified, separated by the * operator, like in ~ v | g1 * g2 * g3. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to ~ 1.

fixed — an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. It must have names identifying which coefficients are to be fixed. Coefficients included in fixed are not allowed to vary during the optimization of an objective function. Defaults to NULL, corresponding to no fixed coefficients.

## Value

a varIdent object representing a constant variance function structure, also inheriting from class varFunc.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

```

---

## Variogram *Calculate Semi-variogram*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `default`, `gls` and `lme`. See the appropriate method documentation for a description of the arguments.

### Usage

```
Variogram(object, distance, ...)
```

### Arguments

| | |
|---|---|
| `object` | a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model. |
| `distance` | a numeric vector with the pairwise distances corresponding to the elements of `object`. The order of the elements in `distance` must correspond to the pairs `(1,2), (1,3), ..., (n-1,n)`, with `n` representing the length of `object`, and must have length `n(n-1)/2`. |
| `...` | some methods for this generic function require additional arguments. |

### Value

will depend on the method function used; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

Variogram.corExp *Calculate Semi-variogram for a corExp Object*

---

## Description

This method function calculates the semi-variogram values corresponding to the Exponential correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

## Usage

```
## S3 method for class 'corExp'
Variogram(object, distance, sig2, length.out, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`corExp`", representing an exponential spatial correlation structure. |
| `distance` | an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to `NULL`, in which case a sequence of length `length.out` between the minimum and maximum values of `getCovariate(object)` is used. |
| `sig2` | an optional numeric value representing the process variance. Defaults to `1`. |
| `length.out` | an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when `distance = NULL`. Defaults to `50`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

# Variogram.corGaus *Calculate Semi-variogram for a corGaus Object*

---

## Description

This method function calculates the semi-variogram values corresponding to the Gaussian correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

## Usage

```
## S3 method for class 'corGaus'
Variogram(object, distance, sig2, length.out, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`corGaus`", representing an Gaussian spatial correlation structure. |
| `distance` | an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to `NULL`, in which case a sequence of length `length.out` between the minimum and maximum values of `getCovariate(object)` is used. |
| `sig2` | an optional numeric value representing the process variance. Defaults to `1`. |
| `length.out` | an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when `distance = NULL`. Defaults to `50`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

---

Variogram.corRatio *Calculate Semi-variogram for a corRatio Object*

---

## Description

This method function calculates the semi-variogram values corresponding to the Rational Quadratic correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

## Usage

```
## S3 method for class 'corRatio'
Variogram(object, distance, sig2, length.out, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class "`corRatio`", representing an Rational Quadratic spatial correlation structure. |
| `distance` | an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to `NULL`, in which case a sequence of length `length.out` between the minimum and maximum values of `getCovariate(object)` is used. |
| `sig2` | an optional numeric value representing the process variance. Defaults to `1`. |
| `length.out` | an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when `distance = NULL`. Defaults to `50`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

## Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

# Variogram.corSpatial *Calculate Semi-variogram for a corSpatial Object*

---

## Description

This method function calculates the semi-variogram values corresponding to the model defined in FUN, using the estimated coefficients corresponding to object, at the distances defined by distance.

## Usage

```
## S3 method for class 'corSpatial'
Variogram(object, distance, sig2, length.out, FUN, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "corSpatial", representing spatial correlation structure. |
| distance | an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used. |
| sig2 | an optional numeric value representing the process variance. Defaults to 1. |
| length.out | an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50. |
| FUN | a function of two arguments, the distance and the range corresponding to object, specifying the semi-variogram model. |
| ... | some methods for this generic require additional arguments. None are used in this method. |

## Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

## Variogram.default *Calculate Semi-variogram*

---

### Description

This method function calculates the semi-variogram for an arbitrary vector `object`, according to the distances in `distance`. For each pair of elements $x, y$ in `object`, the corresponding semi-variogram is $(x-y)^2/2$. The semi-variogram is useful for identifying and modeling spatial correlation structures in observations with constant expectation and constant variance.

### Usage

```
## Default S3 method:
Variogram(object, distance, ...)
```

### Arguments

| | |
|---|---|
| `object` | a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model. |
| `distance` | a numeric vector with the pairwise distances corresponding to the elements of `object`. The order of the elements in `distance` must correspond to the pairs `(1,2), (1,3), ..., (n-1,n)`, with `n` representing the length of `object`, and must have length `n(n-1)/2`. |
| `...` | some methods for this generic require additional arguments. None are used in this method. |

### Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
## Not run:
fm1 <- lm(follicles ~ sin(2 * pi * Time) + cos(2 * pi * Time), Ovary,
          subset = Mare == 1)
Variogram(resid(fm1), dist(1:29))[1:10,]

## End(Not run)
```

---

Variogram.gls *Calculate Semi-variogram for Residuals from a gls Object*

---

## Description

This method function calculates the semi-variogram for the residuals from a `gls` fit. The semi-variogram values are calculated for pairs of residuals within the same group level, if a grouping factor is present. If `collapse` is different from `"none"`, the individual semi-variogram values are collapsed using either a robust estimator (`robust = TRUE`) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

## Usage

```
## S3 method for class 'gls'
Variogram(object, distance, form, resType, data,
      na.action, maxDist, length.out, collapse, nint, breaks,
      robust, metric, ...)
```

## Arguments

| | |
|---|---|
| `object` | an object inheriting from class `"gls"`, representing a generalized least squares fitted model. |
| `distance` | an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments `form`, `data`, and `metric`, unless `object` includes a `corSpatial` element, in which case the associated covariate (obtained with the `getCovariate` method) is used. |
| `form` | an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a `\|` operator in `form`). Default is `~1`, implying that the observation order within the groups is used to obtain the distances. |
| `resType` | an optional character string specifying the type of residuals to be used. If `"response"`, the "raw" residuals (observed - fitted) are used; else, if `"pearson"`, the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if `"normalized"`, the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to `"pearson"`. |

`data` an optional data frame in which to interpret the variables in `form`. By default, the same data used to fit `object` is used.

`na.action` a function that indicates what should happen when the data contain `NA`s. The default action (`na.fail`) causes an error message to be printed and the function to terminate, if there are any incomplete observations.

`maxDist` an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.

`length.out` an optional integer value. When `object` includes a `corSpatial` element, its semi-variogram values are calculated and this argument is used as the `length.out` argument to the corresponding `Variogram` method. Defaults to `50`.

`collapse` an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to `"quantiles"`, the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if `"fixed"`, the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if `"none"`, no collapsing is used and the individual semi-variogram values are returned. Defaults to `"quantiles"`.

`nint` an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to `20`.

`robust` an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If `TRUE` the robust estimator is used. Defaults to `FALSE`.

`breaks` an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in `collapse` is ignored.

`metric` an optional character string specifying the distance metric to be used. The currently available options are `"euclidean"` for the root sum-of-squares of distances; `"maximum"` for the maximum difference; and `"manhattan"` for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to `"euclidean"`.

`...` some methods for this generic require additional arguments. None are used in this method.

## Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, `n.pairs`, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If `object` includes a `corSpatial` element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute `"modelVariog"`. The returned value inherits from class `Variogram`.

---

Variogram.lme *Calculate Semi-variogram for Residuals from an lme Object*

---

## Description

This method function calculates the semi-variogram for the within-group residuals from an lme fit. The semi-variogram values are calculated for pairs of residuals within the same group. If collapse is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (robust = TRUE) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

## Usage

```
## S3 method for class 'lme'
Variogram(object, distance, form, resType, data,
       na.action, maxDist, length.out, collapse, nint, breaks,
       robust, metric, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class "lme", representing a fitted linear mixed-effects model. |
| distance | an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments form, data, and metric, unless object includes a corSpatial element, in which case the associated covariate (obtained with the getCovariate method) is used. |
| form | an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a \| operator in form). Default is ~1, implying that the observation order within the groups is used to obtain the distances. |

`resType` an optional character string specifying the type of residuals to be used. If `"response"`, the "raw" residuals (observed - fitted) are used; else, if `"pearson"`, the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if `"normalized"`, the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to `"pearson"`.

`data` an optional data frame in which to interpret the variables in `form`. By default, the same data used to fit `object` is used.

`na.action` a function that indicates what should happen when the data contain `NA`s. The default action (`na.fail`) causes an error message to be printed and the function to terminate, if there are any incomplete observations.

`maxDist` an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.

`length.out` an optional integer value. When `object` includes a `corSpatial` element, its semi-variogram values are calculated and this argument is used as the `length.out` argument to the corresponding `Variogram` method. Defaults to `50`.

`collapse` an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to `"quantiles"`, the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if `"fixed"`, the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if `"none"`, no collapsing is used and the individual semi-variogram values are returned. Defaults to `"quantiles"`.

`nint` an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to `20`.

`robust` an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If `TRUE` the robust estimator is used. Defaults to `FALSE`.

`breaks` an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in `collapse` is ignored.

`metric` an optional character string specifying the distance metric to be used. The currently available options are `"euclidean"` for the root sum-of-squares of distances; `"maximum"` for the maximum difference; and `"manhattan"` for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to `"euclidean"`.

`...` some methods for this generic require additional arguments. None are used in this method.

## Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, `n.pairs`, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If `object` includes a `corSpatial` element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute `"modelVariog"`. The returned value inherits from class `Variogram`.

## varPower — *Power Variance Function*

---

### Description

This function is a constructor for the varPower class, representing a power variance function structure. Letting $v$ denote the variance covariate and $\sigma^2(v)$ denote the variance function evaluated at $v$, the power variance function is defined as $\sigma^2(v) = |v|^{2\theta}$, where $\theta$ is the variance function coefficient. When a grouping factor is present, a different $\theta$ is used for each factor level.

### Usage

```
varPower(value, form, fixed)
```

### Arguments

| | |
|---|---|
| value | an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in form. If value has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in form. If a grouping factor is present in form and value has length one, its value will be assigned to all grouping levels. Default is numeric(0), which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one). |
| form | an optional one-sided formula of the form ~ v, or ~ v \| g, specifying a variance covariate v and, optionally, a grouping factor g for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ".", representing a fitted model object from which fitted values (fitted(.)) and residuals (resid(.)) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in form, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the * operator, like in ~ v \| g1 * g2 * g3. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to ~ fitted(.) representing a variance covariate given by the fitted values of a fitted model object and no grouping factor. |

`fixed` an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

## Value

a `varPower` object representing a power variance function structure, also inheriting from class `varFunc`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

[.pdMat *Subscript a pdMat Object*

## Description

This method function extracts sub-matrices from the positive-definite matrix represented by x.

## Usage

```
## S3 method for class 'pdMat'
x[i, j, drop = TRUE]
## S3 replacement method for class 'pdMat'
x[i, j] <- value
```

## Arguments

| | |
|---|---|
| x | an object inheriting from class "pdMat" representing a positive-definite matrix. |
| i, j | optional subscripts applying respectively to the rows and columns of the positive-definite matrix represented by object. When i (j) is omitted, all rows (columns) are extracted. |
| drop | a logical value. If TRUE, single rows or columns are converted to vectors. If FALSE the returned value retains its matrix representation. |
| value | a vector, or matrix, with the replacement values for the relevant piece of the matrix represented by x. |

## Value

if i and j are identical, the returned value will be pdMat object with the same class as x. Otherwise, the returned value will be a matrix. In the case a single row (or column) is selected, the returned value may be converted to a vector, according to the rules above.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[, pdMat

## Examples

```
pd1 <- pdSymm(diag(3))
pd1[1, , drop = FALSE]
pd1[1:2, 1:2] <- 3 * diag(2)
```

# Chapter 26

# The nnet package

---

`class.ind` *Generates Class Indicator Matrix from a Factor*

---

### Description

Generates a class indicator function from a given factor.

### Usage

```
class.ind(cl)
```

### Arguments

| | |
|---|---|
| `cl` | factor or vector of classes for cases. |

### Value

a matrix which is zero except for the column corresponding to the class.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

### Examples

```
# The function is currently defined as
class.ind <- function(cl)
{
  n <- length(cl)
  cl <- as.factor(cl)
  x <- matrix(0, n, length(levels(cl)) )
  x[(1:n) + n*(unclass(cl)-1)] <- 1
  dimnames(x) <- list(names(cl), levels(cl))
  x
}
```

multinom *Fit Multinomial Log-linear Models*

## Description

Fits multinomial log-linear models via neural networks.

## Usage

```
multinom(formula, data, weights, subset, na.action,
         contrasts = NULL, Hess = FALSE, summ = 0, censored = FALSE,
         model = FALSE, ...)
```

## Arguments

| | |
|---|---|
| formula | a formula expression as for regression models, of the form `response ~ predictors`. The response should be a factor or a matrix with K columns, which will be interpreted as counts for each of K classes. A log-linear model is fitted, with coefficients zero for the first class. An offset can be included: it should be a numeric matrix with K columns if the response is either a matrix with K columns or a factor with K >= 2 classes, or a numeric vector for a response factor with 2 levels. See the documentation of `formula()` for other details. |
| data | an optional data frame in which to interpret the variables occurring in `formula`. |
| weights | optional case weights in fitting. |
| subset | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default. |
| na.action | a function to filter missing data. |
| contrasts | a list of contrasts to be used for some or all of the factors appearing as variables in the model formula. |
| Hess | logical for whether the Hessian (the observed/expected information matrix) should be returned. |
| summ | integer; if non-zero summarize by deleting duplicate rows and adjust weights. Methods 1 and 2 differ in speed (2 uses `C`); method 3 also combines rows with the same X and different Y, which changes the baseline for the deviance. |
| censored | If Y is a matrix with `K` columns, interpret the entries as one for possible classes, zero for impossible classes, rather than as counts. |
| model | logical. If true, the model frame is saved as component `model` of the returned object. |
| ... | additional arguments for `nnet` |

## Details

`multinom` calls `nnet`. The variables on the rhs of the formula should be roughly scaled to [0,1] or the fit will be slow or may not converge at all.

### Value

A nnet object with additional components:

| | |
|---|---|
| deviance | the residual deviance, compared to the full saturated model (that explains individual observations exactly). Also, minus twice log-likelihood. |
| edf | the (effective) number of degrees of freedom used by the model |
| AIC | the AIC for this fit. |
| Hessian | (if Hess is true). |
| model | (if model is true). |

## nnet *Fit Neural Networks*

---

### Description

Fit single-hidden-layer neural network, possibly with skip-layer connections.

### Usage

```
nnet(x, ...)

## S3 method for class 'formula'
nnet(formula, data, weights, ...,
     subset, na.action, contrasts = NULL)

## Default S3 method:
nnet(x, y, weights, size, Wts, mask,
     linout = FALSE, entropy = FALSE, softmax = FALSE,
     censored = FALSE, skip = FALSE, rang = 0.7, decay = 0,
     maxit = 100, Hess = FALSE, trace = TRUE, MaxNWts = 1000,
     abstol = 1.0e-4, reltol = 1.0e-8, ...)
```

**Arguments**

| | |
|---|---|
| `formula` | A formula of the form `class ~ x1 + x2 + ...` |
| `x` | matrix or data frame of `x` values for examples. |
| `y` | matrix or data frame of target values for examples. |
| `weights` | (case) weights for each example – if missing defaults to 1. |
| `size` | number of units in the hidden layer. Can be zero if there are skip-layer units. |
| `data` | Data frame from which variables specified in `formula` are preferentially to be taken. |
| `subset` | An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.) |
| `na.action` | A function to specify the action to be taken if `NA`s are found. The default action is for the procedure to fail. An alternative is na.omit, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.) |
| `contrasts` | a list of contrasts to be used for some or all of the factors appearing as variables in the model formula. |
| `Wts` | initial parameter vector. If missing chosen at random. |
| `mask` | logical vector indicating which parameters should be optimized (default all). |
| `linout` | switch for linear output units. Default logistic output units. |
| `entropy` | switch for entropy (= maximum conditional likelihood) fitting. Default by least-squares. |
| `softmax` | switch for softmax (log-linear model) and maximum conditional likelihood fitting. `linout`, `entropy`, `softmax` and `censored` are mutually exclusive. |
| `censored` | A variant on `softmax`, in which non-zero targets mean possible classes. Thus for `softmax` a row of `(0, 1, 1)` means one example each of classes 2 and 3, but for `censored` it means one example whose class is only known to be 2 or 3. |
| `skip` | switch to add skip-layer connections from input to output. |
| `rang` | Initial random weights on [-`rang`, `rang`]. Value about 0.5 unless the inputs are large, in which case it should be chosen so that `rang` * max(`\|x\|`) is about 1. |
| `decay` | parameter for weight decay. Default 0. |
| `maxit` | maximum number of iterations. Default 100. |
| `Hess` | If true, the Hessian of the measure of fit at the best set of weights found is returned as component `Hessian`. |
| `trace` | switch for tracing optimization. Default `TRUE`. |
| `MaxNWts` | The maximum allowable number of weights. There is no intrinsic limit in the code, but increasing `MaxNWts` will probably allow fits that are very slow and time-consuming. |
| `abstol` | Stop if the fit criterion falls below `abstol`, indicating an essentially perfect fit. |
| `reltol` | Stop if the optimizer is unable to reduce the fit criterion by a factor of at least `1 - reltol`. |
| `...` | arguments passed to or from other methods. |

## Details

If the response in `formula` is a factor, an appropriate classification network is constructed; this has one output and entropy fit if the number of levels is two, and a number of outputs equal to the number of classes and a softmax output stage for more levels. If the response is not a factor, it is passed on unchanged to `nnet.default`.

Optimization is done via the BFGS method of `optim`.

## Value

object of class `"nnet"` or `"nnet.formula"`. Mostly internal structure, but has components

| | |
|---|---|
| `wts` | the best set of weights found |
| `value` | value of fitting criterion plus weight decay term. |
| `fitted.values` | the fitted values for the training data. |
| `residuals` | the residuals for the training data. |
| `convergence` | `1` if the maximum number of iterations was reached, otherwise `0`. |

## Examples

```
# use half the iris data
ir <- rbind(iris3[,,1],iris3[,,2],iris3[,,3])
targets <- class.ind( c(rep("s", 50), rep("c", 50), rep("v", 50)) )
samp <- c(sample(1:50,25), sample(51:100,25), sample(101:150,25))
ir1 <- nnet(ir[samp,], targets[samp,], size = 2, rang = 0.1,
            decay = 5e-4, maxit = 200)
test.cl <- function(true, pred) {
    true <- max.col(true)
    cres <- max.col(pred)
    table(true, cres)
}
test.cl(targets[-samp,], predict(ir1, ir[-samp,]))

# or
ird <- data.frame(rbind(iris3[,,1], iris3[,,2], iris3[,,3]),
        species = factor(c(rep("s",50), rep("c", 50), rep("v", 50))))
ir.nn2 <- nnet(species ~ ., data = ird, subset = samp, size = 2, rang = 0.1,
               decay = 5e-4, maxit = 200)
table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))
```

nnetHess *Evaluates Hessian for a Neural Network*

## Description

Evaluates the Hessian (matrix of second derivatives) of the specified neural network. Normally called via argument `Hess=TRUE` to `nnet` or via `vcov.multinom`.

## Usage

```
nnetHess(net, x, y, weights)
```

## Arguments

| | |
|---|---|
| `net` | object of class `nnet` as returned by `nnet`. |
| `x` | training data. |
| `y` | classes for training data. |
| `weights` | the (case) weights used in the `nnet` fit. |

## Value

square symmetric matrix of the Hessian evaluated at the weights stored in the net.

## References

Ripley, B. D. (1996) *Pattern Recognition and Neural Networks.* Cambridge.

## Examples

```
# use half the iris data
ir <- rbind(iris3[,,1], iris3[,,2], iris3[,,3])
targets <- matrix(c(rep(c(1,0,0),50), rep(c(0,1,0),50), rep(c(0,0,1),50)),
150, 3, byrow=TRUE)
samp <- c(sample(1:50,25), sample(51:100,25), sample(101:150,25))
ir1 <- nnet(ir[samp,], targets[samp,], size=2, rang=0.1, decay=5e-4, maxit=200)
eigen(nnetHess(ir1, ir[samp,], targets[samp,]), TRUE)$values
```

predict.nnet *Predict New Examples by a Trained Neural Net*

## Description

Predict new examples by a trained neural net.

## Usage

```
## S3 method for class 'nnet'
predict(object, newdata, type = c("raw","class"), ...)
```

## Arguments

| | |
|---|---|
| object | an object of class nnet as returned by nnet. |
| newdata | matrix or data frame of test examples. A vector is considered to be a row vector comprising a single case. |
| type | Type of output |
| ... | arguments passed to or from other methods. |

## Details

This function is a method for the generic function predict() for class "nnet". It can be invoked by calling predict(x) for an object x of the appropriate class, or directly by calling predict.nnet(x) regardless of the class of the object.

## Value

If type = "raw", the matrix of values returned by the trained network; if type = "class", the corresponding class (which is probably only useful if the net was generated by nnet.formula).

## References

Ripley, B. D. (1996) *Pattern Recognition and Neural Networks.* Cambridge.

ir.nn2 <- nnet(species ~ ., data = ird, subset = samp, size = 2, rang = 0.1,
               decay = 5e-4, maxit = 200)
table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))
```

---

`which.is.max` *Find Maximum Position in Vector*

---

## Description

Find the maximum position in a vector, breaking ties at random.

## Usage

```
which.is.max(x)
```

## Arguments

| | |
|---|---|
| x | a vector |

## Details

Ties are broken at random.

## Value

index of a maximal value.

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

## See Also

`max.col`, `which.max` which takes the first of ties.

## Examples

```
## Not run: ## this is incomplete
pred <- predict(nnet, test)
table(true, apply(pred, 1, which.is.max))

## End(Not run)
```

# Chapter 27

# The rpart package

---

car.test.frame *Automobile Data from 'Consumer Reports' 1990*

---

### Description

The car.test.frame data frame has 60 rows and 8 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*. This is part of a larger dataset, some columns of which are given in cu.summary.

### Usage

```
car.test.frame
```

### Format

This data frame contains the following columns:

Price a numeric vector giving the list price in US dollars of a standard model

Country of origin, a factor with levels 'France', 'Germany', 'Japan' , 'Japan/USA', 'Korea', 'Mexico', 'Sweden' and 'USA'

Reliability a numeric vector coded 1 to 5.

Mileage fuel consumption miles per US gallon, as tested.

Type a factor with levels Compact Large Medium Small Sporty Van

Weight kerb weight in pounds.

Disp. the engine capacity (displacement) in litres.

HP the net horsepower of the vehicle.

### Source

*Consumer Reports*, April, 1990, pp. 235–288 quoted in

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA, pp. 46–47.

## See Also

car90, cu.summary

## Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)
```

---

car90 *Automobile Data from 'Consumer Reports' 1990*

---

## Description

Data on 111 cars, taken from pages 235–255, 281–285 and 287–288 of the April 1990 *Consumer Reports* Magazine.

## Usage

```
data(car90)
```

## Format

The data frame contains the following columns

**Country** a factor giving the country in which the car was manufactured

**Disp** engine displacement in cubic inches

**Disp2** engine displacement in liters

**Eng.Rev** engine revolutions per mile, or engine speed at 60 mph

**Front.Hd** distance between the car's head-liner and the head of a 5 ft. 9 in. front seat passenger, in inches, as measured by CU

**Frt.Leg.Room** maximum front leg room, in inches, as measured by CU

**Frt.Shld** front shoulder room, in inches, as measured by CU

**Gear.Ratio** the overall gear ratio, high gear, for manual transmission

**Gear2** the overall gear ratio, high gear, for automatic transmission

**HP** net horsepower

**HP.revs** the red line—the maximum safe engine speed in rpm

**Height** height of car, in inches, as supplied by manufacturer

**Length** overall length, in inches, as supplied by manufacturer

**Luggage** luggage space

**Mileage** a numeric vector of gas mileage in miles/gallon as tested by CU; contains NAs.

**Model2** alternate name, if the car was sold under two labels

**Price** list price with standard equipment, in dollars

**Rear.Hd** distance between the car's head-liner and the head of a 5 ft 9 in. rear seat passenger, in inches, as measured by CU

**Rear.Seating** rear fore-and-aft seating room, in inches, as measured by CU

**RearShld** rear shoulder room, in inches, as measured by CU

**Reliability** an ordered factor with levels 'Much worse' < 'worse' < 'average' < 'better' < 'Much better': contains NAs.

**Rim** factor giving the rim size

**Sratio.m** Number of turns of the steering wheel required for a turn of 30 foot radius, manual steering

**Sratio.p** Number of turns of the steering wheel required for a turn of 30 foot radius, power steering

**Steering** steering type offered: manual, power, or both

**Tank** fuel refill capacity in gallons

**Tires** factor giving tire size

**Trans1** manual transmission, a factor with levels '', 'man.4', 'man.5' and 'man.6'

**Trans2** automatic transmission, a factor with levels '', 'auto.3', 'auto.4', and 'auto.CVT'. No car is missing both the manual and automatic transmission variables, but several had both as options

**Turning** the radius of the turning circle in feet

**Type** a factor giving the general type of car. The levels are: 'Small', 'Sporty', 'Compact', 'Medium', 'Large', 'Van'

**Weight** an order statistic giving the relative weights of the cars; 1 is the lightest and 111 is the heaviest

**Wheel.base** length of wheelbase, in inches, as supplied by manufacturer

**Width** width of car, in inches, as supplied by manufacturer

## Source

This is derived (with permission) from the data set car.all in S-PLUS, but with some further clean up of variable names and definitions.

## See Also

car.test.frame, cu.summary for extracts from other versions of the dataset.

## Examples

```
data(car90)
plot(car90$Price/1000, car90$Weight,
     xlab = "Price (thousands)", ylab = "Weight (lbs)")
mlowess <- function(x, y, ...) {
    keep <- !(is.na(x) | is.na(y))
    lowess(x[keep], y[keep], ...)
}
with(car90, lines(mlowess(Price/1000, Weight, f = 0.5)))
```

cu.summary *Automobile Data from 'Consumer Reports' 1990*

## Description

The cu.summary data frame has 117 rows and 5 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*.

## Usage

```
cu.summary
```

## Format

This data frame contains the following columns:

Price a numeric vector giving the list price in US dollars of a standard model

Country of origin, a factor with levels 'Brazil', 'England', 'France', 'Germany', 'Japan', 'Japan/USA', 'Korea', 'Mexico', 'Sweden' and 'USA'

Reliability an ordered factor with levels 'Much worse' < 'worse' < 'average' < 'better' < 'Much better'

Mileage fuel consumption miles per US gallon, as tested.

Type a factor with levels Compact Large Medium Small Sporty Van

```

## kyphosis — *Data on Children who have had Corrective Spinal Surgery*

### Description

The kyphosis data frame has 81 rows and 4 columns. representing data on children who have had corrective spinal surgery

### Usage

```
kyphosis
```

### Format

This data frame contains the following columns:

- Kyphosis a factor with levels absent present indicating if a kyphosis (a type of deformation) was present after the operation.
- Age in months
- Number the number of vertebrae involved
- Start the number of the first (topmost) vertebra operated on.

### Source

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA.

### Examples

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
              parms = list(prior = c(0.65, 0.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis,
              control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = TRUE)
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
```

## labels.rpart — *Create Split Labels For an Rpart Object*

### Description

This function provides labels for the branches of an rpart tree.

### Usage

```
## S3 method for class 'rpart'
labels(object, digits = 4, minlength = 1L, pretty, collapse = TRUE, ...)
```

### Arguments

| | |
|---|---|
| `object` | fitted model object of class `"rpart"`. This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function. |
| `digits` | the number of digits to be used for numeric values. All of the `rpart` functions that call labels explicitly set this value, with `options("digits")` as the default. |
| `minlength` | the minimum length for abbreviation of character or factor variables. If `0` no abbreviation is done; if `1` single English letters are used, first lower case than upper case (with a maximum of 52 levels). If the value is greater than , the `abbreviate` function is used, passed the `minlength` argument. |
| `pretty` | an argument included for compatibility with the **tree** package: `pretty = 0` implies `minlength = 0L`, `pretty = NULL` implies `minlength = 1L`, and `pretty = TRUE` implies `minlength = 4L`. |
| `collapse` | logical. The returned set of labels is always of the same length as the number of nodes in the tree.<br>If `collapse = TRUE` (default), the returned value is a vector of labels for the branch leading into each node, with `"root"` as the label for the top node.<br>If `FALSE`, the returned value is a two column matrix of labels for the left and right branches leading out from each node, with `"leaf"` as the branch labels for terminal nodes. |
| `...` | optional arguments to `abbreviate`. |

### Value

Vector of split labels (`collapse = TRUE`) or matrix of left and right splits (`collapse = FALSE`) for the supplied `rpart` object. This function is called by printing methods for `rpart` and is not intended to be called directly by the users.

### See Also

`abbreviate`

---

## meanvar.rpart *Mean-Variance Plot for an Rpart Object*

---

### Description

Creates a plot on the current graphics device of the deviance of the node divided by the number of observations at the node. Also returns the node number.

### Usage

```
meanvar(tree, ...)

## S3 method for class 'rpart'
meanvar(tree, xlab = "ave(y)", ylab = "ave(deviance)", ...)
```

### Arguments

| | |
|---|---|
| tree | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |
| xlab | x-axis label for the plot. |
| ylab | y-axis label for the plot. |
| ... | additional graphical parameters may be supplied as arguments to this function. |

### Value

an invisible list containing the following vectors is returned.

| | |
|---|---|
| x | fitted value at terminal nodes (yval). |
| y | deviance of node divided by number of observations at node. |
| label | node number. |

### Side Effects

a plot is put on the current graphics device.

### See Also

plot.rpart.

### Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
meanvar(z.auto, log = 'xy')
```

---

## na.rpart *Handles Missing Values in an Rpart Object*

---

### Description

Handles missing values in an "rpart" object.

### Usage

```
na.rpart(x)
```

### Arguments

| | |
|---|---|
| x | a model frame. |

### Details

Default function that handles missing values when calling the function rpart.

It omits cases where part of the response is missing or all the explanatory variables are missing.

path.rpart *Follow Paths to Selected Nodes of an Rpart Object*

## Description

Returns a names list where each element contains the splits on the path from the root to the selected nodes.

## Usage

```
path.rpart(tree, nodes, pretty = 0, print.it = TRUE)
```

## Arguments

| | |
|---|---|
| tree | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |
| nodes | an integer vector containing indices (node numbers) of all nodes for which paths are desired. If missing, user selects nodes as described below. |
| pretty | an integer denoting the extent to which factor levels in split labels will be abbreviated. A value of (0) signifies no abbreviation. A NULL, the default, signifies using elements of letters to represent the different factor levels. |
| print.it | Logical. Denotes whether paths will be printed out as nodes are interactively selected. Irrelevant if nodes argument is supplied. |

## Details

The function has a required argument as an rpart object and a list of nodes as optional arguments. Omitting a list of nodes will cause the function to wait for the user to select nodes from the dendrogram. It will return a list, with one component for each node specified or selected. The component contains the sequence of splits leading to that node. In the graphical interaction, the individual paths are printed out as nodes are selected.

## Value

A named (by node) list, each element of which contains all the splits on the path from the root to the specified or selected nodes.

## Graphical Interaction

A dendrogram of the rpart object is expected to be visible on the graphics device, and a graphics input device (e.g. a mouse) is required. Clicking (the selection button) on a node selects that node. This process may be repeated any number of times. Clicking the exit button will stop the selection process and return the list of paths.

## References

This function was modified from path.tree in S.

## See Also

rpart

## Examples

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
print(fit)
path.rpart(fit, node = c(11, 22))
```

---

`plot.rpart` *Plot an Rpart Object*

---

## Description

Plots an rpart object on the current graphics device.

## Usage

```
## S3 method for class 'rpart'
plot(x, uniform = FALSE, branch = 1, compress = FALSE, nspace,
     margin = 0, minbranch = 0.3, ...)
```

## Arguments

| | |
|---|---|
| `x` | a fitted object of class `"rpart"`, containing a classification, regression, or rate tree. |
| `uniform` | if `TRUE`, uniform vertical spacing of the nodes is used; this may be less cluttered when fitting a large plot onto a page. The default is to use a non-uniform spacing proportional to the error in the fit. |
| `branch` | controls the shape of the branches from parent to child node. Any number from 0 to 1 is allowed. A value of 1 gives square shouldered branches, a value of 0 give V shaped branches, with other values being intermediate. |
| `compress` | if `FALSE`, the leaf nodes will be at the horizontal plot coordinates of `1:nleaves`. If `TRUE`, the routine attempts a more compact arrangement of the tree. The compaction algorithm assumes `uniform=TRUE`; surprisingly, the result is usually an improvement even when that is not the case. |
| `nspace` | the amount of extra space between a node with children and a leaf, as compared to the minimal space between leaves. Applies to compressed trees only. The default is the value of `branch`. |
| `margin` | an extra fraction of white space to leave around the borders of the tree. (Long labels sometimes get cut off by the default computation). |
| `minbranch` | set the minimum length for a branch to `minbranch` times the average branch length. This parameter is ignored if `uniform=TRUE`. Sometimes a split will give very little improvement, or even (in the classification case) no improvement at all. A tree with branch lengths strictly proportional to improvement leaves no room to squeeze in node labels. |
| `...` | arguments to be passed to or from other methods. |

## Details

This function is a method for the generic function `plot`, for objects of class `rpart`. The y-coordinate of the top node of the tree will always be 1.

### Value

The coordinates of the nodes are returned as a list, with components x and y.

### Side Effects

An unlabeled plot is produced on the current graphics device: one being opened if needed.

In order to build up a plot in the usual S style, e.g., a separate text command for adding labels, some extra information about the plot needs be retained. This is kept in an environment in the package.

### See Also

rpart, text.rpart

### Examples

```
fit <- rpart(Price ~ Mileage + Type + Country, cu.summary)
par(xpd = TRUE)
plot(fit, compress = TRUE)
text(fit, use.n = TRUE)
```

---

## plotcp — *Plot a Complexity Parameter Table for an Rpart Fit*

---

### Description

Gives a visual representation of the cross-validation results in an rpart object.

### Usage

```
plotcp(x, minline = TRUE, lty = 3, col = 1,
       upper = c("size", "splits", "none"), ...)
```

### Arguments

| | |
|---|---|
| x | an object of class "rpart" |
| minline | whether a horizontal line is drawn 1SE above the minimum of the curve. |
| lty | line type for this line |
| col | colour for this line |
| upper | what is plotted on the top axis: the size of the tree (the number of leaves), the number of splits or nothing. |
| ... | additional plotting parameters |

### Details

The set of possible cost-complexity prunings of a tree from a nested set. For the geometric means of the intervals of values of cp for which a pruning is optimal, a cross-validation has (usually) been done in the initial construction by rpart. The cptable in the fit contains the mean and standard deviation of the errors in the cross-validated prediction against each of the geometric means, and these are plotted by this function. A good choice of cp for pruning is often the leftmost value for which the mean lies below the horizontal line.

### Value

None.

### Side Effects

A plot is produced on the current graphical device.

### See Also

rpart, printcp, rpart.object

---

post.rpart *PostScript Presentation Plot of an Rpart Object*

---

### Description

Generates a PostScript presentation plot of an rpart object.

### Usage

```
post(tree, ...)

## S3 method for class 'rpart'
post(tree, title.,
     filename = paste(deparse(substitute(tree)), ".ps", sep = ""),
     digits = getOption("digits") - 2, pretty = TRUE,
     use.n = TRUE, horizontal = TRUE, ...)
```

### Arguments

| | |
|---|---|
| tree | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |
| title. | a title which appears at the top of the plot. By default, the name of the rpart endpoint is printed out. |
| filename | ASCII file to contain the output. By default, the name of the file is the name of the object given by rpart (with the suffix .ps added). If filename = "", the plot appears on the current graphical device. |
| digits | number of significant digits to include in numerical data. |
| pretty | an integer denoting the extent to which factor levels will be abbreviated in the character strings defining the splits; (0) signifies no abbreviation of levels. A NULL signifies using elements of letters to represent the different factor levels. The default (TRUE) indicates the maximum possible abbreviation. |
| use.n | Logical. If TRUE (default), adds to label (\#events level1/ \#events level2/etc. for method class, n for method anova, and \#events/n for methods poisson and exp). |
| horizontal | Logical. If TRUE (default), plot is horizontal. If FALSE, plot appears as landscape. |
| ... | other arguments to the postscript function. |

### Details

The plot created uses the functions `plot.rpart` and `text.rpart` (with the `fancy` option). The settings were chosen because they looked good to us, but other options may be better, depending on the `rpart` object. Users are encouraged to write their own function containing favorite options.

### Side Effects

a plot of `rpart` is created using the `postscript` driver, or the current device if `filename = ""`.

### See Also

`plot.rpart`, `rpart`, `text.rpart`, `abbreviate`

### Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
post(z.auto, file = "")   # display tree on active device
   # now construct postscript version on file "pretty.ps"
   # with no title
post(z.auto, file = "pretty.ps", title = " ")
z.hp <- rpart(Mileage ~ Weight + HP, car.test.frame)
post(z.hp)
```

---

## `predict.rpart` *Predictions from a Fitted Rpart Object*

---

### Description

Returns a vector of predicted responses from a fitted `rpart` object.

### Usage

```
## S3 method for class 'rpart'
predict(object, newdata,
       type = c("vector", "prob", "class", "matrix"),
       na.action = na.pass, ...)
```

### Arguments

| | |
|---|---|
| `object` | fitted model object of class `"rpart"`. This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function. |
| `newdata` | data frame containing the values at which predictions are required. The predictors referred to in the right side of `formula(object)` must be present by name in `newdata`. If missing, the fitted values are returned. |
| `type` | character string denoting the type of predicted value returned. If the `rpart` object is a classification tree, then the default is to return `prob` predictions, a matrix whose columns are the probability of the first, second, etc. class. (This agrees with the default behavior of `tree`). Otherwise, a vector result is returned. |
| `na.action` | a function to determine what should be done with missing values in `newdata`. The default is to pass them down the tree using surrogates in the way selected when the model was built. Other possibilities are `na.omit` and `na.fail`. |
| `...` | further arguments passed to or from other methods. |

## Details

This function is a method for the generic function predict for class "rpart". It can be invoked by calling predict for an object of the appropriate class, or directly by calling predict.rpart regardless of the class of the object.

## Value

A new object is obtained by dropping newdata down the object. For factor predictors, if an observation contains a level not used to grow the tree, it is left at the deepest possible node and frame$yval at the node is the prediction.

If type = "vector":
vector of predicted responses. For regression trees this is the mean response at the node, for Poisson trees it is the estimated response rate, and for classification trees it is the predicted class (as a number).

If type = "prob":
(for a classification tree) a matrix of class probabilities.

If type = "matrix":
a matrix of the full responses (frame$yval2 if this exists, otherwise frame$yval). For regression trees, this is the mean response, for Poisson trees it is the response rate and the number of events at that node in the fitted tree, and for classification trees it is the concatenation of at least the predicted class, the class counts at that node in the fitted tree, and the class probabilities (some versions of **rpart** may contain further columns).

If type = "class":
(for a classification tree) a factor of classifications based on the responses.

## See Also

predict, rpart.object

## Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
predict(z.auto)

fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
predict(fit, type = "prob")   # class probabilities (default)
predict(fit, type = "vector") # level numbers
predict(fit, type = "class")  # factor
predict(fit, type = "matrix") # level number, class frequencies, probabilities

sub <- c(sample(1:50, 25), sample(51:100, 25), sample(101:150, 25))
fit <- rpart(Species ~ ., data = iris, subset = sub)
fit
table(predict(fit, iris[-sub,], type = "class"), iris[-sub, "Species"])
```

---

# print.rpart *Print an Rpart Object*

---

## Description

This function prints an rpart object. It is a method for the generic function print of class "rpart".

## Usage

```
## S3 method for class 'rpart'
print(x, minlength = 0, spaces = 2, cp, digits = getOption("digits"), ...)
```

## Arguments

| | |
|---|---|
| x | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |
| minlength | Controls the abbreviation of labels: see labels.rpart. |
| spaces | the number of spaces to indent nodes of increasing depth. |
| digits | the number of digits of numbers to print. |
| cp | prune all nodes with a complexity less than cp from the printout. Ignored if unspecified. |
| ... | arguments to be passed to or from other methods. |

## Details

This function is a method for the generic function print for class "rpart". It can be invoked by calling print for an object of the appropriate class, or directly by calling print.rpart regardless of the class of the object.

## Side Effects

A semi-graphical layout of the contents of x$frame is printed. Indentation is used to convey the tree topology. Information for each node includes the node number, split, size, deviance, and fitted value. For the "class" method, the class probabilities are also printed.

## See Also

## End(Not run)
```

printcp *Displays CP table for Fitted Rpart Object*

## Description

Displays the cp table for fitted rpart object.

## Usage

```
printcp(x, digits = getOption("digits") - 2)
```

## Arguments

| | |
|---|---|
| x | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |
| digits | the number of digits of numbers to print. |

## Details

Prints a table of optimal prunings based on a complexity parameter.

## See Also

summary.rpart, rpart.object

## Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
printcp(z.auto)
## Not run:

## End(Not run)
```

## prune.rpart — *Cost-complexity Pruning of an Rpart Object*

### Description

Determines a nested sequence of subtrees of the supplied `rpart` object by recursively `snipping` off the least important splits, based on the complexity parameter (`cp`).

### Usage

```
prune(tree, ...)

## S3 method for class 'rpart'
prune(tree, cp, ...)
```

### Arguments

| | |
|---|---|
| `tree` | fitted model object of class `"rpart"`. This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function. |
| `cp` | Complexity parameter to which the `rpart` object will be trimmed. |
| `...` | further arguments passed to or from other methods. |

### Value

A new `rpart` object that is trimmed to the value `cp`.

### See Also

`rpart`

### Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
zp <- prune(z.auto, cp = 0.1)
plot(zp) #plot smaller rpart object
```

## residuals.rpart — *Residuals From a Fitted Rpart Object*

### Description

Method for `residuals` for an `rpart` object.

### Usage

```
## S3 method for class 'rpart'
residuals(object, type = c("usual", "pearson", "deviance"), ...)
```

### Arguments

| | |
|---|---|
| `object` | fitted model object of class "`rpart`". |
| `type` | Indicates the type of residual desired.<br>For regression or `anova` trees all three residual definitions reduce to `y - fitted`. This is the residual returned for `user` method trees as well.<br>For classification trees the `usual` residuals are the misclassification losses L(actual, predicted) where L is the loss matrix. With default losses this residual is 0/1 for correct/incorrect classification. The `pearson` residual is (1-fitted)/sqrt(fitted(1-fitted)) and the `deviance` residual is sqrt(minus twice logarithm of fitted).<br>For `poisson` and `exp` (or survival) trees, the `usual` residual is the observed - expected number of events. The `pearson` and `deviance` residuals are as defined in McCullagh and Nelder. |
| `...` | further arguments passed to or from other methods. |

### Value

Vector of residuals of type `type` from a fitted `rpart` object.

### References

McCullagh P. and Nelder, J. A. (1989) *Generalized Linear Models*. London: Chapman and Hall.

### Examples

```
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
             data = solder, method = "anova")
summary(residuals(fit))
plot(predict(fit),residuals(fit))
```

---

## `rpart` *Recursive Partitioning and Regression Trees*

---

### Description

Fit a `rpart` model

### Usage

```
rpart(formula, data, weights, subset, na.action = na.rpart, method,
      model = FALSE, x = FALSE, y = TRUE, parms, control, cost, ...)
```

### Arguments

| | |
|---|---|
| `formula` | a formula, with a response but no interaction terms. If this a a data frame, that is taken as the model frame (see `model.frame`). |
| `data` | an optional data frame in which to interpret the variables named in the formula. |
| `weights` | optional case weights. |
| `subset` | optional expression saying that only a subset of the rows of the data should be used in the fit. |

`na.action` the default action deletes all observations for which `y` is missing, but keeps those in which one or more predictors are missing.

`method` one of `"anova"`, `"poisson"`, `"class"` or `"exp"`. If `method` is missing then the routine tries to make an intelligent guess. If `y` is a survival object, then `method = "exp"` is assumed, if `y` has 2 columns then `method = "poisson"` is assumed, if `y` is a factor then `method = "class"` is assumed, otherwise `method = "anova"` is assumed. It is wisest to specify the method directly, especially as more criteria may added to the function in future.

Alternatively, `method` can be a list of functions named `init`, `split` and `eval`. Examples are given in the file '`tests/usersplits.R`' in the sources, and in the vignettes 'User Written Split Functions'.

`model` if logical: keep a copy of the model frame in the result? If the input value for `model` is a model frame (likely from an earlier call to the `rpart` function), then this frame is used rather than constructing new data.

`x` keep a copy of the `x` matrix in the result.

`y` keep a copy of the dependent variable in the result. If missing and `model` is supplied this defaults to `FALSE`.

`parms` optional parameters for the splitting function.
Anova splitting has no parameters.
Poisson splitting has a single parameter, the coefficient of variation of the prior distribution on the rates. The default value is 1.
Exponential splitting has the same parameter as Poisson.
For classification splitting, the list can contain any of: the vector of prior probabilities (component `prior`), the loss matrix (component `loss`) or the splitting index (component `split`). The priors must be positive and sum to 1. The loss matrix must have zeros on the diagonal and positive off-diagonal elements. The splitting index can be `gini` or `information`. The default priors are proportional to the data counts, the losses default to 1, and the split defaults to `gini`.

`control` a list of options that control details of the `rpart` algorithm. See `rpart.control`.

`cost` a vector of non-negative costs, one for each variable in the model. Defaults to one for all variables. These are scalings to be applied when considering splits, so the improvement on splitting on a variable is divided by its cost in deciding which split to choose.

`...` arguments to `rpart.control` may also be specified in the call to `rpart`. They are checked against the list of valid arguments.

## Details

This differs from the `tree` function in S mainly in its handling of surrogate variables. In most details it follows Breiman *et. al* (1984) quite closely. R package **tree** provides a re-implementation of `tree`.

## Value

An object of class `rpart`. See `rpart.object`.

## References

Breiman L., Friedman J. H., Olshen R. A., and Stone, C. J. (1984) *Classification and Regression Trees.* Wadsworth.

## See Also

rpart.control, rpart.object, summary.rpart, print.rpart

## Examples

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
              parms = list(prior = c(.65,.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
              control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = NA) # otherwise on some devices the text is clipped
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
```

---

# rpart.control *Control for Rpart Fits*

---

## Description

Various parameters that control aspects of the rpart fit.

## Usage

```
rpart.control(minsplit = 20, minbucket = round(minsplit/3), cp = 0.01,
              maxcompete = 4, maxsurrogate = 5, usesurrogate = 2, xval = 10,
              surrogatestyle = 0, maxdepth = 30, ...)
```

## Arguments

| | |
|---|---|
| minsplit | the minimum number of observations that must exist in a node in order for a split to be attempted. |
| minbucket | the minimum number of observations in any terminal <leaf> node. If only one of minbucket or minsplit is specified, the code either sets minsplit to minbucket*3 or minbucket to minsplit/3, as appropriate. |
| cp | complexity parameter. Any split that does not decrease the overall lack of fit by a factor of cp is not attempted. For instance, with anova splitting, this means that the overall R-squared must increase by cp at each step. The main role of this parameter is to save computing time by pruning off splits that are obviously not worthwhile. Essentially,the user informs the program that any split which does not improve the fit by cp will likely be pruned off by cross-validation, and that hence the program need not pursue it. |
| maxcompete | the number of competitor splits retained in the output. It is useful to know not just which split was chosen, but which variable came in second, third, etc. |
| maxsurrogate | the number of surrogate splits retained in the output. If this is set to zero the compute time will be reduced, since approximately half of the computational time (other than setup) is used in the search for surrogate splits. |

| | |
|---|---|
| usesurrogate | how to use surrogates in the splitting process. 0 means display only; an observation with a missing value for the primary split rule is not sent further down the tree. 1 means use surrogates, in order, to split subjects missing the primary variable; if all surrogates are missing the observation is not split. For value 2 ,if all surrogates are missing, then send the observation in the majority direction. A value of 0 corresponds to the action of tree, and 2 to the recommendations of Breiman *et.al* (1984). |
| xval | number of cross-validations. |
| surrogatestyle | controls the selection of a best surrogate. If set to 0 (default) the program uses the total number of correct classification for a potential surrogate variable, if set to 1 it uses the percent correct, calculated over the non-missing values of the surrogate. The first option more severely penalizes covariates with a large number of missing values. |
| maxdepth | Set the maximum depth of any node of the final tree, with the root node counted as depth 0. Values greater than 30 rpart will give nonsense results on 32-bit machines. |
| ... | mop up other arguments. |

## Value

A list containing the options.

## See Also

rpart

---

rpart.exp *Initialization function for exponential fitting*

---

## Description

This function does the initialization step for rpart, when the response is a survival object. It rescales the data so as to have an exponential baseline hazard and then uses Poisson methods. This function would rarely if ever be called directly by a user.

## Usage

```
rpart.exp(y, offset, parms, wt)
```

## Arguments

| | |
|---|---|
| y | the response, which will be of class Surv |
| offset | optional offset |
| parms | parameters controlling the fit. This is a list with components shrink and method. The first is the prior for the coefficient of variation of the predictions. The second is either "deviance" or "sqrt" and is the measure used for cross-validation. If values are missing the defaults are used, which are "deviance" for the method, and a shrinkage of 1.0 for the deviance method and 0 for the square root. |
| wt | case weights, if present |

### Value

a list with the necessary initialization components

### Author(s)

Terry Therneau

### See Also

rpart

---

rpart.object *Recursive Partitioning and Regression Trees Object*

---

### Description

These are objects representing fitted rpart trees.

### Value

frame
: data frame with one row for each node in the tree. The row.names of frame contain the (unique) node numbers that follow a binary ordering indexed by node depth. Columns of frame include var, a factor giving the names of the variables used in the split at each node (leaf nodes are denoted by the level "<leaf>"), n, the number of observations reaching the node, wt, the sum of case weights for observations reaching the node, dev, the deviance of the node, yval, the fitted value of the response at the node, and splits, a two column matrix of left and right split labels for each node. Also included in the frame are complexity, the complexity parameter at which this split will collapse, ncompete, the number of competitor splits recorded, and nsurrogate, the number of surrogate splits recorded.

  Extra response information which may be present is in yval2, which contains the number of events at the node (poisson tree), or a matrix containing the fitted class, the class counts for each node, the class probabilities and the 'node probability' (classification trees).

where
: an integer vector of the same length as the number of observations in the root node, containing the row number of frame corresponding to the leaf node that each observation falls into.

call
: an image of the call that produced the object, but with the arguments all named and with the actual formula included as the formula argument. To re-evaluate the call, say update(tree).

terms
: an object of class c("terms", "formula") (see terms.object) summarizing the formula. Used by various methods, but typically not of direct relevance to users.

splits
: a numeric matrix describing the splits: only present if there are any. The row label is the name of the split variable, and columns are count, the number of observations (which are not missing and are of positive weight) sent left or right by the split (for competitor splits this is the number that would have been sent left or right had this split been used, for surrogate splits it is the number missing the primary split variable which were decided using this surrogate), ncat,

the number of categories or levels for the variable (+/-1 for a continuous variable), improve, which is the improvement in deviance given by this split, or, for surrogates, the concordance of the surrogate with the primary, and index, the numeric split point. The last column adj gives the adjusted concordance for surrogate splits. For a factor, the index column contains the row number of the csplit matrix. For a continuous variable, the sign of ncat determines whether the subset x < cutpoint or x > cutpoint is sent to the left.

csplit — an integer matrix. (Only present only if at least one of the split variables is a factor or ordered factor.) There is a row for each such split, and the number of columns is the largest number of levels in the factors. Which row is given by the index column of the splits matrix. The columns record 1 if that level of the factor goes to the left, 3 if it goes to the right, and 2 if that level is not present at this node of the tree (or not defined for the factor).

method — character string: the method used to grow the tree. One of "class", "exp", "poisson", "anova" or "user" (if splitting functions were supplied).

cptable — a matrix of information on the optimal prunings based on a complexity parameter.

variable.importance — a named numeric vector giving the importance of each variable. (Only present if there are any splits.) When printed by summary.rpart these are rescaled to add to 100.

numresp — integer number of responses; the number of levels for a factor response.

parms, control — a record of the arguments supplied, which defaults filled in.

functions — the summary, print and text functions for method used.

ordered — a named logical vector recording for each variable if it was an ordered factor.

na.action — (where relevant) information returned by model.frame on the special handling of NAs derived from the na.action argument.

There may be attributes "xlevels" and "levels" recording the levels of any factor splitting variables and of a factor response respectively.

Optional components include the model frame (model), the matrix of predictors (x) and the response variable (y) used to construct the rpart object.

## Structure

The following components must be included in a legitimate rpart object.

## See Also

rpart.

---

rsq.rpart *Plots the Approximate R-Square for the Different Splits*

---

## Description

Produces 2 plots. The first plots the r-square (apparent and apparent - from cross-validation) versus the number of splits. The second plots the Relative Error(cross-validation) +/- 1-SE from cross-validation versus the number of splits.

### Usage

```
rsq.rpart(x)
```

### Arguments

| | |
|---|---|
| x | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |

### Side Effects

Two plots are produced.

### Note

The labels are only appropriate for the "anova" method.

### Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
rsq.rpart(z.auto)
```

---

## snip.rpart *Snip Subtrees of an Rpart Object*

---

### Description

Creates a "snipped" rpart object, containing the nodes that remain after selected subtrees have been snipped off. The user can snip nodes using the toss argument, or interactively by clicking the mouse button on specified nodes within the graphics window.

### Usage

```
snip.rpart(x, toss)
```

### Arguments

| | |
|---|---|
| x | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |
| toss | an integer vector containing indices (node numbers) of all subtrees to be snipped off. If missing, user selects branches to snip off as described below. |

### Details

A dendrogram of rpart is expected to be visible on the graphics device, and a graphics input device (e.g., a mouse) is required. Clicking (the selection button) on a node displays the node number, sample size, response y-value, and Error (dev). Clicking a second time on the same node snips that subtree off and visually erases the subtree. This process may be repeated an number of times. Warnings result from selecting the root or leaf nodes. Clicking the exit button will stop the snipping process and return the resulting rpart object.

See the documentation for the specific graphics device for details on graphical input techniques.

## Value

A rpart object containing the nodes that remain after specified or selected subtrees have been snipped off.

## Warning

Visually erasing the plot is done by over-plotting with the background colour. This will do nothing if the background is transparent (often true for screen devices).

## See Also

plot.rpart

## Examples

```
## dataset not in R
## Not run:
z.survey <- rpart(market.survey) # grow the rpart object
plot(z.survey) # plot the tree
z.survey2 <- snip.rpart(z.survey, toss = 2) # trim subtree at node 2
plot(z.survey2) # plot new tree

# can also interactively select the node using the mouse in the
# graphics window

## End(Not run)
```

---

solder *Soldering of Components on Printed-Circuit Boards*

---

## Description

The solder data frame has 720 rows and 6 columns, representing a balanced subset of a designed experiment varying 5 factors on the soldering of components on printed-circuit boards.

## Usage

```
solder
```

## Format

This data frame contains the following columns:

Opening a factor with levels 'L', 'M' and 'S' indicating the amount of clearance around the mounting pad.

Solder a factor with levels 'Thick' and 'Thin' giving the thickness of the solder used.

Mask a factor with levels 'A1.5', 'A3', 'B3' and 'B6' indicating the type and thickness of mask used.

PadType a factor with levels 'D4', 'D6', 'D7', 'L4', 'L6', 'L7', 'L8', 'L9', 'W4' and 'W9' giving the size and geometry of the mounting pad.

Panel 1:3 indicating the panel on a board being tested.

skips a numeric vector giving the number of visible solder skips.

## Source

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA.

## Examples

```
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
             data = solder, method = "anova")
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```

---

`stagec` *Stage C Prostate Cancer*

---

## Description

A set of 146 patients with stage C prostate cancer, from a study exploring the prognostic value of flow cytometry.

## Usage

```
data(stagec)
```

## Format

A data frame with 146 observations on the following 8 variables.

`pgtime` Time to progression or last follow-up (years)

`pgstat` 1 = progression observed, 0 = censored

`age` age in years

`eet` early endocrine therapy, 1 = no, 2 = yes

`g2` percent of cells in G2 phase, as found by flow cytometry

`grade` grade of the tumor, Farrow system

`gleason` grade of the tumor, Gleason system

`ploidy` the ploidy status of the tumor, from flow cytometry. Values are '`diploid`', '`tetraploid`', and '`aneuploid`'

## Details

A tumor is called diploid (normal complement of dividing cells) if the fraction of cells in G2 phase was determined to be 13% or less. Aneuploid cells have a measurable fraction with a chromosome count that is neither 24 nor 48, for these the G2 percent is difficult or impossible to measure.

## Examples

```
require(survival)
rpart(Surv(pgtime, pgstat) ~ ., stagec)
```

summary.rpart *Summarize a Fitted Rpart Object*

## Description

Returns a detailed listing of a fitted rpart object.

## Usage

```
## S3 method for class 'rpart'
summary(object, cp = 0, digits = getOption("digits"), file, ...)
```

## Arguments

| | |
|---|---|
| object | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |
| digits | Number of significant digits to be used in the result. |
| cp | trim nodes with a complexity of less than cp from the listing. |
| file | write the output to a given file name. (Full listings of a tree are often quite long). |
| ... | arguments to be passed to or from other methods. |

## Details

This function is a method for the generic function summary for class "rpart". It can be invoked by calling summary for an object of the appropriate class, or directly by calling summary.rpart regardless of the class of the object.

It prints the call, the table shown by printcp, the variable importance (summing to 100) and details for each node (the details depending on the type of tree).

## See Also

summary, rpart.object, printcp.

## Examples

```
## a regression tree
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)

## a classification tree with multiple variables and surrogate splits.
summary(rpart(Kyphosis ~ Age + Number + Start, data = kyphosis))
```

text.rpart *Place Text on a Dendrogram Plot*

## Description

Labels the current plot of the tree dendrogram with text.

## Usage

```
## S3 method for class 'rpart'
text(x, splits = TRUE, label, FUN = text, all = FALSE,
     pretty = NULL, digits = getOption("digits") - 3, use.n = FALSE,
     fancy = FALSE, fwidth = 0.8, fheight = 0.8, bg = par("bg"),
     minlength = 1L, ...)
```

## Arguments

| | |
|---|---|
| x | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |
| splits | logical flag. If TRUE (default), then the splits in the tree are labeled with the criterion for the split. |
| label | For compatibility with rpart2, ignored in this version (with a warning). |
| FUN | the name of a labeling function, e.g. text. |
| all | Logical. If TRUE, all nodes are labeled, otherwise just terminal nodes. |
| minlength | the length to use for factor labels. A value of 1 causes them to be printed as 'a', 'b', ..... Larger values use abbreviations of the label names. See the labels.rpart function for details. |
| pretty | an alternative to the minlength argument, see labels.rpart. |
| digits | number of significant digits to include in numerical labels. |
| use.n | Logical. If TRUE, adds to label (\#events level1/ \#events level2/etc. for class, n for anova, and \#events/n for poisson and exp). |
| fancy | Logical. If TRUE, nodes are represented by ellipses (interior nodes) and rectangles (leaves) and labeled by yval. The edges connecting the nodes are labeled by left and right splits. |
| fwidth | Relates to option fancy and the width of the ellipses and rectangles. If fwidth < 1 then it is a scaling factor (default = 0.8). If fwidth > 1 then it represents the number of character widths (for current graphical device) to use. |
| fheight | Relates to option fancy and the height of the ellipses and rectangles. If fheight <1 then it is a scaling factor (default = 0.8). If fheight > 1 then it represents the number of character heights (for current graphical device) to use. |
| bg | The color used to paint the background to annotations if fancy = TRUE. |
| ... | Graphical parameters may also be supplied as arguments to this function (see par). As labels often extend outside the plot region it can be helpful to specify xpd = TRUE. |

### Side Effects

the current plot of a tree dendrogram is labeled.

### See Also

text, plot.rpart, rpart, labels.rpart, abbreviate

### Examples

```
freen.tr <- rpart(y ~ ., freeny)
par(xpd = TRUE)
plot(freen.tr)
text(freen.tr, use.n = TRUE, all = TRUE)
```

---

## xpred.rpart *Return Cross-Validated Predictions*

---

### Description

Gives the predicted values for an rpart fit, under cross validation, for a set of complexity parameter values.

### Usage

```
xpred.rpart(fit, xval = 10, cp, return.all = FALSE)
```

### Arguments

| | |
|---|---|
| fit | a object of class "rpart". |
| xval | number of cross-validation groups. This may also be an explicit list of integers that define the cross-validation groups. |
| cp | the desired list of complexity values. By default it is taken from the cptable component of the fit. |
| return.all | if FALSE return only the first element of the prediction |

### Details

Complexity penalties are actually ranges, not values. If the cp values found in the table were .36, .28, and .13, for instance, this means that the first row of the table holds for all complexity penalties in the range $[.36, 1]$, the second row for cp in the range $[.28, .36)$ and the third row for $[.13, .28)$. By default, the geometric mean of each interval is used for cross validation.

### Value

A matrix with one row for each observation and one column for each complexity value. If return.all is TRUE and the prediction for each node is a vector, then the result will be an array containing all of the predictions. When the response is categorical, for instance, the result contains the predicted class followed by the class probabilities of the selected terminal node; result[1,,] will be the matrix of predicted classes, result[2,,] the matrix of class 1 probabilities, etc.

## See Also

rpart

## Examples

```
fit <- rpart(Mileage ~ Weight, car.test.frame)
xmat <- xpred.rpart(fit)
xerr <- (xmat - car.test.frame$Mileage)^2
apply(xerr, 2, sum)   # cross-validated error estimate

# approx same result as rel. error from printcp(fit)
apply(xerr, 2, sum)/var(car.test.frame$Mileage)
printcp(fit)
```

# Chapter 28

# The spatial package

---

anova.trls *Anova tables for fitted trend surface objects*

---

### Description

Compute analysis of variance tables for one or more fitted trend surface model objects; where anova.trls is called with multiple objects, it passes on the arguments to anovalist.trls.

### Usage

```
## S3 method for class 'trls'
anova(object, ...)
anovalist.trls(object, ...)
```

### Arguments

| | |
|---|---|
| object | A fitted trend surface model object from surf.ls |
| ... | Further objects of the same kind |

### Value

anova.trls and anovalist.trls return objects corresponding to their printed tabular output.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

surf.ls

## Examples

```
library(stats)
data(topo, package="MASS")
topo0 <- surf.ls(0, topo)
topo1 <- surf.ls(1, topo)
topo2 <- surf.ls(2, topo)
topo3 <- surf.ls(3, topo)
topo4 <- surf.ls(4, topo)
anova(topo0, topo1, topo2, topo3, topo4)
summary(topo4)
```

---

# correlogram *Compute Spatial Correlograms*

---

## Description

Compute spatial correlograms of spatial data or residuals.

## Usage

```
correlogram(krig, nint, plotit = TRUE,  ...)
```

## Arguments

| | |
|---|---|
| `krig` | trend-surface or kriging object with columns `x`, `y`, and `z` |
| `nint` | number of bins used |
| `plotit` | logical for plotting |
| `...` | parameters for the plot |

## Details

Divides range of data into `nint` bins, and computes the covariance for pairs with separation in each bin, then divides by the variance. Returns results for bins with 6 or more pairs.

## Value

`x` and `y` coordinates of the correlogram, and `cnt`, the number of pairs averaged per bin.

## Side Effects

Plots the correlogram if `plotit = TRUE`.

## References

## Examples

```
data(topo, package="MASS")
topo.kr <- surf.ls(2, topo)
correlogram(topo.kr, 25)
d <- seq(0, 7, 0.1)
lines(d, expcov(d, 0.7))
```

---

expcov *Spatial Covariance Functions*

---

## Description

Spatial covariance functions for use with `surf.gls`.

## Usage

```
expcov(r, d, alpha = 0, se = 1)
gaucov(r, d, alpha = 0, se = 1)
sphercov(r, d, alpha = 0, se = 1, D = 2)
```

## Arguments

| | |
|---|---|
| `r` | vector of distances at which to evaluate the covariance |
| `d` | range parameter |
| `alpha` | proportion of nugget effect |
| `se` | standard deviation at distance zero |
| `D` | dimension of spheres. |

## Value

vector of covariance values.

## References

lines(d, expcov(d, 0.7))
```

Kaver *Average K-functions from Simulations*

## Description

Forms the average of a series of (usually simulated) K-functions.

## Usage

```
Kaver(fs, nsim, ...)
```

## Arguments

| | |
|---|---|
| fs | full scale for K-fn |
| nsim | number of simulations |
| ... | arguments to simulate one point process object |

## Value

list with components x and y of the average K-fn on L-scale.

## References

Ripley, B. D. (1981) *Spatial Statistics.* Wiley.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

lines(lims$x,lims$lower, lty=2, col="green")
lines(lims$x,lims$upper, lty=2, col="green")
lines(Kaver(10,25,Strauss(69,0.5,3.5)),  col="red")
```

Kenvl *Compute Envelope and Average of Simulations of K-fns*

## Description

Computes envelope (upper and lower limits) and average of simulations of K-fns

## Usage

```
Kenvl(fs, nsim, ...)
```

## Arguments

| | |
|---|---|
| fs | full scale for K-fn |
| nsim | number of simulations |
| ... | arguments to produce one simulation |

## Value

list with components

| | |
|---|---|
| x | distances |
| lower | min of K-fns |
| upper | max of K-fns |
| aver | average of K-fns |

## References

lines(Kaver(10,25,Strauss(69,0.5,3.5)), col="red")
```

Kfn *Compute K-fn of a Point Pattern*

## Description

Actually computes $L = \sqrt{K/\pi}$.

## Usage

```
Kfn(pp, fs, k=100)
```

## Arguments

| | |
|---|---|
| pp | a list such as a pp object, including components x and y |
| fs | full scale of the plot |
| k | number of regularly spaced distances in (0, fs) |

## Details

relies on the domain D having been set by ppinit or ppregion.

## Value

A list with components

| | |
|---|---|
| x | vector of distances |
| y | vector of L-fn values |
| k | number of distances returned – may be less than k if fs is too large |
| dmin | minimum distance between pair of points |
| lm | maximum deviation from L(t) = t |

## References

towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="s", xlab="distance", ylab="L(t)")
```

## ppgetregion — *Get Domain for Spatial Point Pattern Analyses*

### Description

Retrieves the rectangular domain `(xl, xu)` × `(yl, yu)` from the underlying `C` code.

### Usage

```
ppgetregion()
```

### Value

A vector of length four with names `c("xl", "xu", "yl", "yu")`.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

### See Also

`ppregion`

## ppinit — *Read a Point Process Object from a File*

### Description

Read a file in standard format and create a point process object.

### Usage

```
ppinit(file)
```

### Arguments

| | |
|---|---|
| `file` | string giving file name |

### Details

The file should contain

the number of points
a header (ignored)
xl xu yl yu scale
x y (repeated n times)

### Value

class `"pp"` object with components `x`, `y`, `xl`, `xu`, `yl`, `yu`

### Side Effects

Calls `ppregion` to set the domain.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

### See Also

`ppregion`

### Examples

```
towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="b", xlab="distance", ylab="L(t)")
```

---

## pplik — *Pseudo-likelihood Estimation of a Strauss Spatial Point Process*

---

### Description

Pseudo-likelihood estimation of a Strauss spatial point process.

### Usage

```
pplik(pp, R, ng=50, trace=FALSE)
```

### Arguments

| | |
|---|---|
| `pp` | a pp object |
| `R` | the fixed parameter `R` |
| `ng` | use a `ng` x `ng` grid with border `R` in the domain for numerical integration. |
| `trace` | logical? Should function evaluations be printed? |

### Value

estimate for `c` in the interval $[0, 1]$.

### References

Ripley, B. D. (1988) *Statistical Inference for Spatial Processes.* Cambridge.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

### See Also

`Strauss`

### Examples

```
pines <- ppinit("pines.dat")
pplik(pines, 0.7)
```

## ppregion — *Set Domain for Spatial Point Pattern Analyses*

### Description

Sets the rectangular domain `(xl, xu)` × `(yl, yu)`.

### Usage

```
ppregion(xl = 0, xu = 1, yl = 0, yu = 1)
```

### Arguments

| | |
|---|---|
| `xl` | Either `xl` or a list containing components `xl`, `xu`, `yl`, `yu` (such as a point-process object) |
| `xu` | |
| `yl` | |
| `yu` | |

### Value

none

### Side Effects

initializes variables in the `C` subroutines.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

### See Also

`ppinit`, `ppgetregion`

## predict.trls — *Predict method for trend surface fits*

### Description

Predicted values based on trend surface model object

### Usage

```
## S3 method for class 'trls'
predict(object, x, y, ...)
```

### Arguments

| | |
|---|---|
| object | Fitted trend surface model object returned by surf.ls |
| x | Vector of prediction location eastings (x coordinates) |
| y | Vector of prediction location northings (y coordinates) |
| ... | further arguments passed to or from other methods. |

### Value

predict.trls produces a vector of predictions corresponding to the prediction locations. To display the output with image or contour, use trmat or convert the returned vector to matrix form.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

### See Also

surf.ls, trmat

### Examples

```
data(topo, package="MASS")
topo2 <- surf.ls(2, topo)
topo4 <- surf.ls(4, topo)
x <- c(1.78, 2.21)
y <- c(6.15, 6.15)
z2 <- predict(topo2, x, y)
z4 <- predict(topo4, x, y)
cat("2nd order predictions:", z2, "\n4th order predictions:", z4, "\n")
```

---

## prmat — *Evaluate Kriging Surface over a Grid*

---

### Description

Evaluate Kriging surface over a grid.

### Usage

```
prmat(obj, xl, xu, yl, yu, n)
```

### Arguments

| | |
|---|---|
| obj | object returned by surf.gls |
| xl | limits of the rectangle for grid |
| xu | |
| yl | |
| yu | |
| n | use n x n grid within the rectangle |

### Value

list with components x, y and z suitable for contour and image.

### References

Ripley, B. D. (1981) *Spatial Statistics.* Wiley.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

### See Also

surf.gls, trmat, semat

### Examples

```
data(topo, package="MASS")
topo.kr <- surf.gls(2, expcov, topo, d=0.7)
prsurf <- prmat(topo.kr, 0, 6.5, 0, 6.5, 50)
contour(prsurf, levels=seq(700, 925, 25))
```

---

## Psim — *Simulate Binomial Spatial Point Process*

---

### Description

Simulate Binomial spatial point process.

### Usage

```
Psim(n)
```

### Arguments

| | |
|---|---|
| n | number of points |

### Details

relies on the region being set by ppinit or ppregion.

### Value

list of vectors of x and y coordinates.

### Side Effects

uses the random number generator.

### References

Ripley, B. D. (1981) *Spatial Statistics.* Wiley.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

```

---

semat *Evaluate Kriging Standard Error of Prediction over a Grid*

---

## Description

Evaluate Kriging standard error of prediction over a grid.

## Usage

```
semat(obj, xl, xu, yl, yu, n, se)
```

## Arguments

| | |
|---|---|
| obj | object returned by surf.gls |
| xl | limits of the rectangle for grid |
| xu | |
| yl | |
| yu | |
| n | use n x n grid within the rectangle |
| se | standard error at distance zero as a multiple of the supplied covariance. Otherwise estimated, and it assumed that a correlation function was supplied. |

## Value

list with components x, y and z suitable for contour and image.

## References

Ripley, B. D. (1981) *Spatial Statistics.* Wiley.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

prsurf <- prmat(topo.kr, 0, 6.5, 0, 6.5, 50)
contour(prsurf, levels=seq(700, 925, 25))
sesurf <- semat(topo.kr, 0, 6.5, 0, 6.5, 30)
contour(sesurf, levels=c(22,25))
```

---

SSI *Simulates Sequential Spatial Inhibition Point Process*

---

## Description

Simulates SSI (sequential spatial inhibition) point process.

## Usage

```
SSI(n, r)
```

## Arguments

| | |
|---|---|
| n | number of points |
| r | inhibition distance |

## Details

uses the region set by `ppinit` or `ppregion`.

## Value

list of vectors of `x` and `y` coordinates

## Side Effects

uses the random number generator.

## Warnings

will never return if `r` is too large and it cannot place `n` points.

## References

Ripley, B. D. (1981) *Spatial Statistics.* Wiley.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

## Examples

```
towns <- ppinit("towns.dat")
par(pty = "s")
plot(Kfn(towns, 10), type = "b", xlab = "distance", ylab = "L(t)")
lines(Kaver(10, 25, SSI(69, 1.2)))
```

---

`Strauss` *Simulates Strauss Spatial Point Process*

---

## Description

Simulates Strauss spatial point process.

## Usage

```
Strauss(n, c=0, r)
```

## Arguments

| | |
|---|---|
| `n` | number of points |
| `c` | parameter `c` in $[0, 1]$. `c = 0` corresponds to complete inhibition at distances up to `r`. |
| `r` | inhibition distance |

## Details

Uses spatial birth-and-death process for 4n steps, or for 40n steps starting from a binomial pattern on the first call from an other function. Uses the region set by `ppinit` or `ppregion`.

## Value

list of vectors of $x$ and $y$ coordinates

## Side Effects

uses the random number generator

## References

Ripley, B. D. (1981) *Spatial Statistics.* Wiley.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

```

surf.gls *Fits a Trend Surface by Generalized Least-squares*

## Description

Fits a trend surface by generalized least-squares.

## Usage

```
surf.gls(np, covmod, x, y, z, nx = 1000, ...)
```

## Arguments

| | |
|---|---|
| np | degree of polynomial surface |
| covmod | function to evaluate covariance or correlation function |
| x | x coordinates or a data frame with columns x, y, z |
| y | y coordinates |
| z | z coordinates. Will supersede x$z |
| nx | Number of bins for table of the covariance. Increasing adds accuracy, and increases size of the object. |
| ... | parameters for covmod |

## Value

list with components

| | |
|---|---|
| beta | the coefficients |
| x | |
| y | |
| z | and others for internal use only. |

## References

Ripley, B. D. (1981) *Spatial Statistics.* Wiley.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S.* Fourth edition. Springer.

```

---

`surf.ls` *Fits a Trend Surface by Least-squares*

---

## Description

Fits a trend surface by least-squares.

## Usage

```
surf.ls(np, x, y, z)
```

## Arguments

| | |
|---|---|
| `np` | degree of polynomial surface |
| `x` | x coordinates or a data frame with columns `x`, `y`, `z` |
| `y` | y coordinates |
| `z` | z coordinates. Will supersede `x$z` |

## Value

list with components

| | |
|---|---|
| `beta` | the coefficients |
| `x` | |
| `y` | |
| `z` | and others for internal use only. |

```

---

`trls.influence` *Regression diagnostics for trend surfaces*

---

## Description

This function provides the basic quantities which are used in forming a variety of diagnostics for checking the quality of regression fits for trend surfaces calculated by `surf.ls`.

## Usage

```
trls.influence(object)
## S3 method for class 'trls'
plot(x, border = "red", col = NA, pch = 4, cex = 0.6,
     add = FALSE, div = 8, ...)
```

## Arguments

| | |
|---|---|
| `object, x` | Fitted trend surface model from `surf.ls` |
| `div` | scaling factor for influence circle radii in `plot.trls` |
| `add` | add influence plot to existing graphics if `TRUE` |
| `border, col, pch, cex, ...` | additional graphical parameters |

## Value

`trls.influence` returns a list with components:

| | |
|---|---|
| `r` | raw residuals as given by `residuals.trls` |
| `hii` | diagonal elements of the Hat matrix |
| `stresid` | standardised residuals |
| `Di` | Cook's statistic |

```

---

# trmat *Evaluate Trend Surface over a Grid*

---

## Description

Evaluate trend surface over a grid.

## Usage

```
trmat(obj, xl, xu, yl, yu, n)
```

## Arguments

| | |
|---|---|
| obj | object returned by surf.ls or surf.gls |
| xl | limits of the rectangle for grid |
| xu | |
| yl | |
| yu | |
| n | use n x n grid within the rectangle |

## Value

list with components x, y and z suitable for contour and image.

---

`variogram` *Compute Spatial Variogram*

---

## Description

Compute spatial (semi-)variogram of spatial data or residuals.

## Usage

```
variogram(krig, nint, plotit = TRUE, ...)
```

## Arguments

| | |
|---|---|
| `krig` | trend-surface or kriging object with columns `x`, `y`, and `z` |
| `nint` | number of bins used |
| `plotit` | logical for plotting |
| `...` | parameters for the plot |

## Details

Divides range of data into `nint` bins, and computes the average squared difference for pairs with separation in each bin. Returns results for bins with 6 or more pairs.

## Value

`x` and `y` coordinates of the variogram and `cnt`, the number of pairs averaged per bin.

## Side Effects

Plots the variogram if `plotit = TRUE`

# Chapter 29

# The survival package

---

aareg *Aalen's additive regression model for censored data*

---

### Description

Returns an object of class "aareg" that represents an Aalen model.

### Usage

```
aareg(formula, data, weights, subset, na.action,
   qrtol=1e-07, nmin, dfbeta=FALSE, taper=1,
   test = c('aalen', 'variance', 'nrisk'),
    model=FALSE, x=FALSE, y=FALSE)
```

### Arguments

| | |
|---|---|
| formula | a formula object, with the response on the left of a '~' operator and the terms, separated by + operators, on the right. The response must be a Surv object. Due to a particular computational approach that is used, the model MUST include an intercept term. If "-1" is used in the model formula the program will ignore it. |
| data | data frame in which to interpret the variables named in the formula, subset, and weights arguments. This may also be a single number to handle some speci al cases – see below for details. If data is missing, the variables in the model formula should be in the search path. |
| weights | vector of observation weights. If supplied, the fitting algorithm minimizes the sum of the weights multiplied by the squared residuals (see below for additional technical details). The length of weights must be the same as the number of observations. The weights must be nonnegative and it i s recommended that they be strictly positive, since zero weights are ambiguous. To exclude particular observations from the model, use the subset argument instead of zero weights. |
| subset | expression specifying which subset of observations should be used in the fit. Th is can be a logical vector (which is replicated to have length equal to the numb er of observations), a numeric vector indicating the observation numbers to be included, or a character vector of the observation names that should be included. All observations are included by default. |

| | |
|---|---|
| na.action | a function to filter missing data. This is applied to the model.fr ame after any subset argument has be en applied. The default is na.fail, which returns a n error if any missing values are found. An alternative is na.excl ude, which deletes observations that contain one or more missing values. |
| qrtol | tolerance for detection of singularity in the QR decomposition |
| nmin | minimum number of observations for an estimate; defaults to 3 times the number of covariates. This essentially truncates the computations near the tail of the data set, when n is small and the calculations can become numerically unstable. |
| dfbeta | should the array of dfbeta residuals be computed. This implies computation of the sandwich variance estimate. The residuals will always be computed if there is a cluster term in the model formula. |
| taper | allows for a smoothed variance estimate. Var(x), where x is the set of covariates, is an important component of the calculations for the Aalen regression model. At any given time point t, it is computed over all subjects who are still at risk at time t. The tape argument allows smoothing these estimates, for example taper=(1:4)/4 would cause the variance estimate used at any event time to be a weighted average of the estimated variance matrices at the last 4 death times, with a weight of 1 for the current death time and decreasing to 1/4 for prior event times. The default value gives the standard Aalen model. |
| test | selects the weighting to be used, for computing an overall "average" coefficient vector over time and the subsequent test for equality to zero. |
| model, x, y | should copies of the model frame, the x matrix of predictors, or the response vector y be included in the saved result. |

## Details

The Aalen model assumes that the cumulative hazard H(t) for a subject can be expressed as a(t) + X B(t), where a(t) is a time-dependent intercept term, X is the vector of covariates for the subject (possibly time-dependent), and B(t) is a time-dependent matrix of coefficients. The estimates are inherently non-parametric; a fit of the model will normally be followed by one or more plots of the estimates.

The estimates may become unstable near the tail of a data set, since the increment to B at time t is based on the subjects still at risk at time t. The tolerance and/or nmin parameters may act to truncate the estimate before the last death. The taper argument can also be used to smooth out the tail of the curve. In practice, the addition of a taper such as 1:10 appears to have little effect on death times when n is still reasonably large, but can considerably dampen wild occilations in the tail of the plot.

## Value

an object of class "aareg" representing the fit, with the following components:

| | |
|---|---|
| n | vector containing the number of observations in the data set, the number of event times, and the number of event times used in the computation |
| times | vector of sorted event times, which may contain duplicates |
| nrisk | vector containing the number of subjects at risk, of the same length as times |
| coefficient | matrix of coefficients, with one row per event and one column per covariate |
| test.statistic | the value of the test statistic, a vector with one element per covariate |
| test.var | variance-covariance matrix for the test |
| test | the type of test; a copy of the test argument above |
| tweight | matrix of weights used in the computation, one row per event |
| call | a copy of the call that produced this result |

---

aeqSurv *Adjudicate near ties in a Surv object*

---

## Description

The check for tied survival times can fail due to floating point imprecision, which can make actual ties appear to be distinct values. Routines that depend on correct identification of ties pairs will then give incorrect results, e.g., a Cox model. This function rectifies these.

## Usage

```
aeqSurv(x, tolerance = sqrt(.Machine$double.eps))
```

## Arguments

| | |
|---|---|
| x | a Surv object |
| tolerance | the tolerance used to detect values that will be considered equal |

## Details

This routine is called by both `survfit` and `coxph` to deal with the issue of ties that get incorrectly broken due to floating point imprecision. See the short vignette on tied times for a simple example. Use the `timefix` argument of `survfit` or `coxph.control` to control the option if desired.

The rule for 'equality' is identical to that used by the `all.equal` routine. Pairs of values that are within round off error of each other are replaced by the smaller value. An error message is generated if this process causes a 0 length time interval to be created.

## Value

a Surv object identical to the original, but with ties restored.

## Author(s)

Terry Therneau

## See Also

`survfit`, `coxph.control`

agreg.fit *Cox model fitting functions*

## Description

These are the the functions called by coxph that do the actual computation. In certain situations, e.g. a simulation, it may be advantageous to call these directly rather than the usual coxph call using a model formula.

## Usage

```
agreg.fit(x, y, strata, offset, init, control, weights, method, rownames)
coxph.fit(x, y, strata, offset, init, control, weights, method, rownames)
```

## Arguments

| | |
|---|---|
| x | Matix of predictors. This should *not* include an intercept. |
| y | a Surv object containing either 2 columns (coxph.fit) or 3 columns (agreg.fit). |
| strata | a vector containing the stratification, or NULL |
| offset | optional offset vector |
| init | initial values for the coefficients |
| control | the result of a call to coxph.control |
| weights | optional vector of weights |
| method | method for hanling ties, one of "breslow" or "efron" |
| rownames | this is only needed for a NULL model, in which case it contains the rownames (if any) of the original data. |

## Details

This routine does no checking that arguments are the proper length or type. Only use it if you know what you are doing!

## Value

a list containing results of the fit

## Author(s)

Terry Therneau

coxph

## aml — *Acute Myelogenous Leukemia survival data*

### Description

Survival in patients with Acute Myelogenous Leukemia. The question at the time was whether the standard course of chemotherapy should be extended ('maintainance') for additional cycles.

### Usage

```
aml
leukemia
```

### Format

| | |
|---|---|
| time: | survival or censoring time |
| status: | censoring status |
| x: | maintenance chemotherapy given? (factor) |

### Source

Rupert G. Miller (1997), *Survival Analysis*. John Wiley & Sons. ISBN: 0-471-25218-2.

## anova.coxph — *Analysis of Deviance for a Cox model.*

### Description

Compute an analysis of deviance table for one or more Cox model fits.

### Usage

```
## S3 method for class 'coxph'
anova(object, ...,  test = 'Chisq')
```

### Arguments

| | |
|---|---|
| `object` | An object of class `coxph` |
| `...` | Further `coxph` objects |
| `test` | a character string. The appropriate test is a chisquare, all other choices result in no test being done. |

### Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the model log-likelihood as each term of the formula is added in turn are given in as the rows of a table, plus the log-likelihoods themselves. A robust variance estimate is normally used in situations where the model may be mis-specified, e.g., multiple events per subject. In this case a comparison of partial-likelihood values does not make sense, and `anova` will refuse to print results.

If more than one object is specified, the table has a row for the degrees of freedom and loglikelihood for each model. For all but the first model, the change in degrees of freedom and loglik is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in loglik for each row.

### Value

An object of class `"anova"` inheriting from class `"data.frame"`.

### Warning

The comparison between two or more models by `anova` or will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values.

### See Also

`coxph`, `anova`.

### Examples

```
fit <- coxph(Surv(futime, fustat) ~ resid.ds *rx + ecog.ps, data = ovarian)
anova(fit)
fit2 <- coxph(Surv(futime, fustat) ~ resid.ds +rx + ecog.ps, data=ovarian)
anova(fit2,fit)
```

---

## `attrassign` *Create new-style "assign" attribute*

---

### Description

The `"assign"` attribute on model matrices describes which columns come from which terms in the model formula. It has two versions. R uses the original version, but the alternate version found in S-plus is sometimes useful.

### Usage

```
## Default S3 method:
attrassign(object, tt,...)
## S3 method for class 'lm'
attrassign(object,...)
```

## Arguments

| | |
|---|---|
| `object` | model matrix or linear model object |
| `tt` | terms object |
| `...` | ignored |

## Details

For instance consider the following

```
survreg(Surv(time, status) ~ age + sex + factor(ph.ecog), lung)
```

R gives the compact for for assign, a vector (0, 1, 2, 3, 3, 3); which can be read as "the first column of the X matrix (intercept) goes with none of the terms, the second column of X goes with term 1 of the model equation, the third column of X with term 2, and columns 4-6 with term 3".

The alternate (S-Plus default) form is a list

```
$(Intercept)     1
$age             2
$sex             3
$factor(ph.ecog) 4 5 6
```

## Value

A list with names corresponding to the term names and elements that are vectors indicating which columns come from which terms

## See Also

`terms`,`model.matrix`

## Examples

```
formula <- Surv(time,status)~factor(ph.ecog)
tt <- terms(formula)
mf <- model.frame(tt,data=lung)
mm <- model.matrix(tt,mf)
## a few rows of data
mm[1:3,]
## old-style assign attribute
attr(mm,"assign")
## alternate style assign attribute
attrassign(mm,tt)
```

basehaz *Alias for the survfit function*

## Description

Compute the predicted survival curve for a Cox model.

## Usage

```
basehaz(fit, centered=TRUE)
```

## Arguments

| | |
|---|---|
| fit | a coxph fit |
| centered | if TRUE return data from a predicted survival curve at the mean values of the covariates fit$mean, if FALSE return a prediction for all covariates equal to zero. |

## Details

This function is simply an alias for survfit, which is the actual function that does all the computations. See the manual page for that function for the preferred use. This function survives only for backwards support of prior usage.

The function returns a data frame containing the time, cumhaz and optionally the strata (if the fitted Cox model used a strata statement), which are copied the survfit result. If there are factor variables in the model, then the default predictions at the "mean" are meaningless since they do not correspond to any possible subject; correct results require use of the newdata argument of survfit. Results for all covariates =0 are normally only of use as a building block for further calculations.

## Value

a data frame with variable names of hazard, time and optionally strata. The first is actually the cumulative hazard.

## See Also

survfit.coxph

bladder *Bladder Cancer Recurrences*

## Description

Data on recurrences of bladder cancer, used by many people to demonstrate methodology for recurrent event modelling.

Bladder1 is the full data set from the study. It contains all three treatment arms and all recurrences for 118 subjects; the maximum observed number of recurrences is 9.

Bladder is the data set that appears most commonly in the literature. It uses only the 85 subjects with nonzero follow-up who were assigned to either thiotepa or placebo, and only the first four recurrences for any patient. The status variable is 1 for recurrence and 0 for everything else (including death for any reason). The data set is laid out in the competing risks format of the paper by Wei, Lin, and Weissfeld.

Bladder2 uses the same subset of subjects as bladder, but formatted in the (start, stop] or Anderson-Gill style. Note that in transforming from the WLW to the AG style data set there is a quite common programming mistake that leads to extra follow-up time for 12 subjects: all those with follow-up beyond their 4th recurrence. This "follow-up" is a side effect of throwing away all events after the fourth while retaining the last follow-up time variable from the original data. The bladder2 data set found here does not make this mistake, but some analyses in the literature have done so; it results in the addition of a small amount of immortal time bias and shrinks the fitted coefficients towards zero.

## Usage

```
bladder1
bladder
bladder2
```

## Format

bladder1

| | |
|---|---|
| id: | Patient id |
| treatment: | Placebo, pyridoxine (vitamin B6), or thiotepa |
| number: | Initial number of tumours (8=8 or more) |
| size: | Size (cm) of largest initial tumour |
| recur: | Number of recurrences |
| start,stop: | The start and end time of each time interval |
| status: | End of interval code, 0=censored, 1=recurrence, 2=death from bladder disease, 3=death other/unknown cause |
| rtumor: | Number of tumors found at the time of a recurrence |
| rsize: | Size of largest tumor at a recurrence |
| enum: | Event number (observation number within patient) |

bladder

| | |
|---|---|
| id: | Patient id |
| rx: | Treatment 1=placebo 2=thiotepa |
| number: | Initial number of tumours (8=8 or more) |
| size: | size (cm) of largest initial tumour |
| stop: | recurrence or censoring time |
| enum: | which recurrence (up to 4) |

bladder2

| | |
|---|---|
| id: | Patient id |
| rx: | Treatment 1=placebo 2=thiotepa |
| number: | Initial number of tumours (8=8 or more) |
| size: | size (cm) of largest initial tumour |
| start: | start of interval (0 or previous recurrence time) |
| stop: | recurrence or censoring time |
| enum: | which recurrence (up to 4) |

Andrews DF, Hertzberg AM (1985), DATA: A Collection of Problems from Many Fields for the Student and Research Worker, New York: Springer-Verlag.

LJ Wei, DY Lin, L Weissfeld (1989), Regression analysis of multivariate incomplete failure time data by modeling marginal distributions. *Journal of the American Statistical Association*, **84**.

---

`cch` *Fits proportional hazards regression model to case-cohort data*

---

## Description

Returns estimates and standard errors from relative risk regression fit to data from case-cohort studies. A choice is available among the Prentice, Self-Prentice and Lin-Ying methods for unstratified data. For stratified data the choice is between Borgan I, a generalization of the Self-Prentice estimator for unstratified case-cohort data, and Borgan II, a generalization of the Lin-Ying estimator.

## Usage

```
cch(formula, data = sys.parent(), subcoh, id, stratum=NULL, cohort.size,
    method =c("Prentice","SelfPrentice","LinYing","I.Borgan","II.Borgan"),
    robust=FALSE)
```

## Arguments

| | |
|---|---|
| `formula` | A formula object that must have a `Surv` object as the response. The Surv object must be of type `"right"`, or of type `"counting"`. |
| `subcoh` | Vector of indicators for subjects sampled as part of the sub-cohort. Code `1` or `TRUE` for members of the sub-cohort, `0` or `FALSE` for others. If `data` is a data frame then `subcoh` may be a one-sided formula. |
| `id` | Vector of unique identifiers, or formula specifying such a vector. |
| `stratum` | A vector of stratum indicators or a formula specifying such a vector |
| `cohort.size` | Vector with size of each stratum original cohort from which subcohort was sampled |
| `data` | An optional data frame in which to interpret the variables occurring in the formula. |
| `method` | Three procedures are available. The default method is "Prentice", with options for "SelfPrentice" or "LinYing". |
| `robust` | For `"LinYing"` only, if `robust=TRUE`, use design-based standard errors even for phase I |

## Details

Implements methods for case-cohort data analysis described by Therneau and Li (1999). The three methods differ in the choice of "risk sets" used to compare the covariate values of the failure with those of others at risk at the time of failure. "Prentice" uses the sub-cohort members "at risk" plus the failure if that occurs outside the sub-cohort and is score unbiased. "SelfPren" (Self-Prentice) uses just the sub-cohort members "at risk". These two have the same asymptotic variance-covariance matrix. "LinYing" (Lin-Ying) uses the all members of the sub-cohort and all failures outside the sub-cohort who are "at risk". The methods also differ in the weights given to different score contributions.

The `data` argument must not have missing values for any variables in the model. There must not be any censored observations outside the subcohort.

## Value

An object of class "cch" incorporating a list of estimated regression coefficients and two estimates of their asymptotic variance-covariance matrix.

| | |
|---|---|
| `coef` | regression coefficients. |
| `naive.var` | Self-Prentice model based variance-covariance matrix. |
| `var` | Lin-Ying empirical variance-covariance matrix. |

cgd *Chronic Granulotomous Disease data*

---

## Description

Data are from a placebo controlled trial of gamma interferon in chronic granulotomous disease (CGD). Contains the data on time to serious infections observed through end of study for each patient.

## Usage

```
cgd
```

## Format

**id** subject identification number

**center** enrolling center

**random** date of randomization

**treatment** placebo or gamma interferon

**sex** sex

**age** age in years, at study entry

**height** height in cm at study entry

**weight** weight in kg at study entry

**inherit** pattern of inheritance

**steroids** use of steroids at study entry,1=yes

**propylac** use of prophylactic antibiotics at study entry

**hos.cat** a categorization of the centers into 4 groups

**tstart, tstop** start and end of each time interval

**status** 1=the interval ends with an infection

**enum** observation number within subject

## Details

The `cgd0` data set is in the form found in the references, with one line per patient and no recoding of the variables. The `cgd` data set (this one) has been cast into (start, stop] format with one line per event, and covariates such as center recoded as factors to include meaningful labels.

`cgd0` *Chronic Granulotomous Disease data*

---

## Description

Data are from a placebo controlled trial of gamma interferon in chronic granulotomous disease (CGD). Contains the data on time to serious infections observed through end of study for each patient.

## Usage

```
cgd0
```

### Format

**id** subject identification number

**center** enrolling center

**random** date of randomization

**treatment** placebo or gamma interferon

**sex** sex

**age** age in years, at study entry

**height** height in cm at study entry

**weight** weight in kg at study entry

**inherit** pattern of inheritance

**steroids** use of steroids at study entry,1=yes

**propylac** use of prophylactic antibiotics at study entry

**hos.cat** a categorization of the centers into 4 groups

**futime** days to last follow-up

**etime1-etime7** up to 7 infection times for the subject

### Details

The `cgdraw` data set (this one) is in the form found in the references, with one line per patient and no recoding of the variables.

The `cgd` data set has been further processed so as to have one line per event, with covariates such as center recoded as factors to include meaningful labels.

## `cipoisson` *Confidence limits for the Poisson*

---

### Description

Confidence interval calculation for Poisson rates.

### Usage

```
cipoisson(k, time = 1, p = 0.95, method = c("exact", "anscombe"))
```

### Arguments

| | |
|---|---|
| `k` | Number of successes |
| `time` | Total time on trial |
| `p` | Probability level for the (two-sided) interval |
| `method` | The method for computing the interval. |

## Details

The likelihood method is based on equation 10.10 of Feller, which relates poisson probabilities to tail area of the gamma distribution. The Anscombe approximation is based on the fact that sqrt(k + 3/8) is has a nearly constant variance of 1/4, along with a continuity correction.

There are many other proposed intervals: Patil and Kulkarni list and evaluate 19 different suggestions from the literature!. The exact intervals can be overly broad for very small values of `k`, many of the other approaches try to shrink the lengths, with varying success.

## Value

a vector, matrix, or array. If both `k` and `time` are single values the result is a vector of length 2 containing the lower an upper limits. If either or both are vectors the result is a matrix with two columns. If `k` is a matrix or array, the result will be an array with one more dimension; in this case the dimensions and dimnames (if any) of `k` are preserved.

# [1] 0.02499961
```

---

`clogit` *Conditional logistic regression*

---

## Description

Estimates a logistic regression model by maximising the conditional likelihood. Uses a model formula of the form `case.status~exposure+strata(matched.set)`. The default is to use the exact conditional likelihood, a commonly used approximate conditional likelihood is provided for compatibility with older software.

## Usage

```
clogit(formula, data, weights, subset, na.action,
 method=c("exact", "approximate", "efron", "breslow"),
 ...)
```

## Arguments

| | |
|---|---|
| `formula` | Model formula |
| `data` | data frame |
| `weights` | optional, names the variable containing case weights |
| `subset` | optional, subset the data |
| `na.action` | optional na.action argument. By default the global option `na.action` is used. |
| `method` | use the correct (exact) calculation in the conditional likelihood or one of the approximations |
| `...` | optional arguments, which will be passed to `coxph.control` |

## Details

It turns out that the loglikelihood for a conditional logistic regression model = loglik from a Cox model with a particular data structure. Proving this is a nice homework exercise for a PhD statistics class; not too hard, but the fact that it is true is surprising.

When a well tested Cox model routine is available many packages use this 'trick' rather than writing a new software routine from scratch, and this is what the clogit routine does. In detail, a stratified Cox model with each case/control group assigned to its own stratum, time set to a constant, status of 1=case 0=control, and using the exact partial likelihood has the same likelihood formula as a conditional logistic regression. The clogit routine creates the necessary dummy variable of times (all 1) and the strata, then calls coxph.

The computation of the exact partial likelihood can be very slow, however. If a particular strata had say 10 events out of 20 subjects we have to add up a denominator that involves all possible ways of choosing 10 out of 20, which is 20!/(10! 10!) = 184756 terms. Gail et al describe a fast recursion method which partly ameliorates this; it was incorporated into version 2.36-11 of the survival package. The computation remains infeasible for very large groups of ties, say 100 ties out of 500 subjects, and may even lead to integer overflow for the subscripts – in this latter case the routine will refuse to undertake the task. The Efron approximation is normally a sufficiently accurate substitute.

Most of the time conditional logistic modeling is applied data with 1 case + k controls per set, in which case all of the approximations for ties lead to exactly the same result. The 'approximate' option maps to the Breslow approximation for the Cox model, for historical reasons.

Case weights are not allowed when the exact option is used, as the likelihood is not defined for fractional weights. Even with integer case weights it is not clear how they should be handled. For instance if there are two deaths in a strata, one with weight=1 and one with weight=2, should the likelihood calculation consider all subsets of size 2 or all subsets of size 3? Consequently, case weights are ignored by the routine in this case.

## Value

An object of class `"clogit"`, which is a wrapper for a `"coxph"` object.

clogit(case ~ tocc + tocc:education + strata(id), logan2)
```

---

`cluster` *Identify clusters.*

---

## Description

This is a special function used in the context of survival models. It identifies correlated groups of observations, and is used on the right hand side of a formula. Using `cluster()` in a formula implies that robust sandwich variance estimators are desired.

## Usage

```
cluster(x)
```

## Arguments

| | |
|---|---|
| x | A character, factor, or numeric variable. |

## Details

The function's only action is semantic, to mark a variable as the cluster indicator. The resulting variance is what is known as the "working independence" variance in a GEE model. Note that one cannot use both a frailty term and a cluster term in the same model, the first is a mixed-effects approach to correlation and the second a GEE approach, and these don't mix.

### Value

x

### See Also

coxph, survreg

### Examples

```
marginal.model <- coxph(Surv(time, status) ~ rx + cluster(litter), rats,
                        subset=(sex=='f'))
frailty.model  <- coxph(Surv(time, status) ~ rx + frailty(litter), rats,
                        subset=(sex=='f'))
```

---

## colon — *Chemotherapy for Stage B/C colon cancer*

---

### Description

These are data from one of the first successful trials of adjuvant chemotherapy for colon cancer. Levamisole is a low-toxicity compound previously used to treat worm infestations in animals; 5-FU is a moderately toxic (as these things go) chemotherapy agent. There are two records per person, one for recurrence and one for death

### Usage

```
colon
```

### Format

| | |
|---|---|
| id: | id |
| study: | 1 for all patients |
| rx: | Treatment - Obs(ervation), Lev(amisole), Lev(amisole)+5-FU |
| sex: | 1=male |
| age: | in years |
| obstruct: | obstruction of colon by tumour |
| perfor: | perforation of colon |
| adhere: | adherence to nearby organs |
| nodes: | number of lymph nodes with detectable cancer |
| time: | days until event or censoring |
| status: | censoring status |
| differ: | differentiation of tumour (1=well, 2=moderate, 3=poor) |
| extent: | Extent of local spread (1=submucosa, 2=muscle, 3=serosa, 4=contiguous structures) |
| surg: | time from surgery to registration (0=short, 1=long) |
| node4: | more than 4 positive lymph nodes |
| etype: | event type: 1=recurrence,2=death |

## Note

The study is originally described in Laurie (1989). The main report is found in Moertel (1990). This data set is closest to that of the final report in Moertel (1991). A version of the data with less follow-up time was used in the paper by Lin (1994).

---

`cox.zph` *Test the Proportional Hazards Assumption of a Cox Regression*

---

## Description

Test the proportional hazards assumption for a Cox regression model fit (`coxph`).

## Usage

```
cox.zph(fit, transform="km", global=TRUE)
```

## Arguments

| | |
|---|---|
| `fit` | the result of fitting a Cox regression model, using the `coxph` function. |
| `transform` | a character string specifying how the survival times should be transformed before the test is performed. Possible values are `"km"`, `"rank"`, `"identity"` or a function of one argument. |
| `global` | should a global chi-square test be done, in addition to the per-variable tests. |

## Value

an object of class `"cox.zph"`, with components:

| | |
|---|---|
| `table` | a matrix with one row for each variable, and optionally a last row for the global test. Columns of the matrix contain the correlation coefficient between transformed survival time and the scaled Schoenfeld residuals, a chi-square, and the two-sided p-value. For the global test there is no appropriate correlation, so an NA is entered into the matrix as a placeholder. |

| | |
|---|---|
| x | the transformed time axis. |
| y | the matrix of scaled Schoenfeld residuals. There will be one column per variable and one row per event. The row labels contain the original event times (for the identity transform, these will be the same as x). |
| call | the calling sequence for the routine. |

The computations require the original x matrix of the Cox model fit. Thus it saves time if the x=TRUE option is used in coxph. This function would usually be followed by both a plot and a print of the result. The plot gives an estimate of the time-dependent coefficient beta(t). If the proportional hazards assumption is true, beta(t) will be a horizontal line. The printout gives a test for slope=0.

## See Also

coxph, Surv.

## Examples

```
fit <- coxph(Surv(futime, fustat) ~ age + ecog.ps,
             data=ovarian)
temp <- cox.zph(fit)
print(temp)                  # display the results
plot(temp)                   # plot curves
```

---

coxph *Fit Proportional Hazards Regression Model*

---

## Description

Fits a Cox proportional hazards regression model. Time dependent variables, time dependent strata, multiple events per subject, and other extensions are incorporated using the counting process formulation of Andersen and Gill.

## Usage

```
coxph(formula, data=, weights, subset,
      na.action, init, control,
      ties=c("efron","breslow","exact"),
      singular.ok=TRUE, robust=FALSE,
      model=FALSE, x=FALSE, y=TRUE, tt, method, ...)
```

## Arguments

| | |
|---|---|
| formula | a formula object, with the response on the left of a ~ operator, and the terms on the right. The response must be a survival object as returned by the Surv function. |

| | |
|---|---|
| data | a data.frame in which to interpret the variables named in the formula, or in the subset and the weights argument. |
| weights | vector of case weights. For a thorough discussion of these see the book by Therneau and Grambsch. |
| subset | expression indicating which subset of the rows of data should be used in the fit. All observations are included by default. |
| na.action | a missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is options()$na.action. |
| init | vector of initial values of the iteration. Default initial value is zero for all variables. |
| control | Object of class coxph.control specifying iteration limit and other control options. Default is coxph.control(...). |
| ties | a character string specifying the method for tie handling. If there are no tied death times all the methods are equivalent. Nearly all Cox regression programs use the Breslow method by default, but not this one. The Efron approximation is used as the default here, it is more accurate when dealing with tied death times, and is as efficient computationally. The "exact partial likelihood" is equivalent to a conditional logistic model, and is appropriate when the times are a small set of discrete values. See further below. |
| singular.ok | logical value indicating how to handle collinearity in the model matrix. If TRUE, the program will automatically skip over columns of the X matrix that are linear combinations of earlier columns. In this case the coefficients for such columns will be NA, and the variance matrix will contain zeros. For ancillary calculations, such as the linear predictor, the missing coefficients are treated as zeros. |
| robust | this argument has been deprecated, use a cluster term in the model instead. (The two options accomplish the same goal – creation of a robust variance – but the second is more flexible). |
| model | logical value: if TRUE, the model frame is returned in component model. |
| x | logical value: if TRUE, the x matrix is returned in component x. |
| y | logical value: if TRUE, the response vector is returned in component y. |
| tt | optional list of time-transform functions. |
| method | alternate name for the ties argument. |
| ... | Other arguments will be passed to coxph.control |

## Details

The proportional hazards model is usually expressed in terms of a single survival time value for each person, with possible censoring. Andersen and Gill reformulated the same problem as a counting process; as time marches onward we observe the events for a subject, rather like watching a Geiger counter. The data for a subject is presented as multiple rows or "observations", each of which applies to an interval of observation (start, stop].

The routine internally scales and centers data to avoid overflow in the argument to the exponential function. These actions do not change the result, but lead to more numerical stability. However, arguments to offset are not scaled since there are situations where a large offset value is a purposefully used. Users should not use normally allow large numeric offset values.

## Value

an object of class coxph representing the fit. See coxph.object for details.

### Side Effects

Depending on the call, the `predict`, `residuals`, and `survfit` routines may need to reconstruct the x matrix created by `coxph`. It is possible for this to fail, as in the example below in which the predict function is unable to find `tform`.

```
tfun <- function(tform) coxph(tform, data=lung)
fit <- tfun(Surv(time, status) ~ age)
predict(fit)
```

In such a case add the `model=TRUE` option to the `coxph` call to obviate the need for reconstruction, at the expense of a larger `fit` object.

### Special terms

There are three special terms that may be used in the model equation. A `strata` term identifies a stratified Cox model; separate baseline hazard functions are fit for each strata. The `cluster` term is used to compute a robust variance for the model. The term `+ cluster(id)` where each value of `id` is unique is equivalent to specifying the `robust=T` argument. If the `id` variable is not unique, it is assumed that it identifies clusters of correlated observations. The robust estimate arises from many different arguments and thus has had many labels. It is variously known as the Huber sandwich estimator, White's estimate (linear models/econometrics), the Horvitz-Thompson estimate (survey sampling), the working independence variance (generalized estimating equations), the infinitesimal jackknife, and the Wei, Lin, Weissfeld (WLW) estimate.

A time-transform term allows variables to vary dynamically in time. In this case the `tt` argument will be a function or a list of functions (if there are more than one tt() term in the model) giving the appropriate transform. See the examples below.

### Convergence

In certain data cases the actual MLE estimate of a coefficient is infinity, e.g., a dichotomous variable where one of the groups has no events. When this happens the associated coefficient grows at a steady pace and a race condition will exist in the fitting routine: either the log likelihood converges, the information matrix becomes effectively singular, an argument to exp becomes too large for the computer hardware, or the maximum number of interactions is exceeded. (Nearly always the first occurs.) The routine attempts to detect when this has happened, not always successfully. The primary consequence for he user is that the Wald statistic = coefficient/se(coefficient) is not valid in this case and should be ignored; the likelihood ratio and score tests remain valid however.

### Ties

There are three possible choices for handling tied event times. The Breslow approximation is the easiest to program and hence became the first option coded for almost all computer routines. It then ended up as the default option when other options were added in order to "maintain backwards compatability". The Efron option is more accurate if there are a large number of ties, and it is the default option here. In practice the number of ties is usually small, in which case all the methods are statistically indistinguishable.

Using the "exact partial likelihood" approach the Cox partial likelihood is equivalent to that for matched logistic regression. (The `clogit` function uses the `coxph` code to do the fit.) It is technically appropriate when the time scale is discrete and has only a few unique values, and some packages refer to this as the "discrete" option. There is also an "exact marginal likelihood" due to Prentice which is not implemented here.

The calculation of the exact partial likelihood is numerically intense. Say for instance 15 of 180 subjects at risk had an event on day 7; then the code needs to compute sums over all 180-choose-15 > 10^43 different possible subsets of size 15. There is an efficient recursive algorithm for this task, but even with this the computation can be insufferably long. With (start, stop) data it is much worse since the recursion needs to start anew for each unique start time.

## Penalized regression

coxph can now maximise a penalised partial likelihood with arbitrary user-defined penalty. Supplied penalty functions include ridge regression (ridge), smoothing splines (pspline), and frailty models (frailty).

```

---

coxph.control *Ancillary arguments for controlling coxph fits*

---

## Description

This is used to set various numeric parameters controlling a Cox model fit. Typically it would only be used in a call to coxph.

## Usage

```
coxph.control(eps = 1e-09, toler.chol = .Machine$double.eps^0.75,
iter.max = 20, toler.inf = sqrt(eps), outer.max = 10, timefix=TRUE)
```

## Arguments

| | |
|---|---|
| eps | Iteration continues until the relative change in the log partial likelihood is less than eps. Must be positive. |
| toler.chol | Tolerance for detection of singularity during a Cholesky decomposition of the variance matrix, i.e., for detecting a redundant predictor variable. |
| iter.max | Maximum number of iterations to attempt for convergence. |
| toler.inf | Tolerance criteria for the warning message about a possible infinite coefficient value. |
| outer.max | For a penalized coxph model, e.g. with pspline terms, there is an outer loop of iteration to determine the penalty parameters; maximum number of iterations for this outer loop. |
| timefix | Resolve any near ties in the time variables. (Floating point representation error can cause actual tied times to appear distinct.) |

## Value

a list containing the values of each of the above constants

## Author(s)

Terry Therneau

## See Also

coxph

`coxph.detail` *Details of a Cox Model Fit*

## Description

Returns the individual contributions to the first and second derivative matrix, at each unique event time.

## Usage

```
coxph.detail(object, riskmat=FALSE)
```

## Arguments

| | |
|---|---|
| `object` | a Cox model object, i.e., the result of `coxph`. |
| `riskmat` | include the at-risk indicator matrix in the output? |

## Details

This function may be useful for those who wish to investigate new methods or extensions to the Cox model. The example below shows one way to calculate the Schoenfeld residuals.

## Value

a list with components

| | |
|---|---|
| `time` | the vector of unique event times |
| `nevent` | the number of events at each of these time points. |
| `means` | a matrix with one row for each event time and one column for each variable in the Cox model, containing the weighted mean of the variable at that time, over all subjects still at risk at that time. The weights are the risk weights `exp(x %*% fit$coef)`. |
| `nrisk` | number of subjects at risk. |
| `score` | the contribution to the score vector (first derivative of the log partial likelihood) at each time point. |
| `imat` | the contribution to the information matrix (second derivative of the log partial likelihood) at each time point. |
| `hazard` | the hazard increment. Note that the hazard and variance of the hazard are always for some particular future subject. This routine uses `object$mean` as the future subject. |
| `varhaz` | the variance of the hazard increment. |
| `x,y` | copies of the input data. |
| `strata` | only present for a stratified Cox model, this is a table giving the number of time points of component `time` that were contributed by each of the strata. |
| `riskmat` | a matrix with one row for each time and one column for each observation containing a 0/1 value to indicate whether that observation was (1) or was not (0) at risk at the given time point. |

## See Also

coxph, residuals.coxph

## Examples

```
fit   <- coxph(Surv(futime,fustat) ~ age + rx + ecog.ps, ovarian, x=TRUE)
fitd  <- coxph.detail(fit)
#  There is one Schoenfeld residual for each unique death.  It is a
# vector (covariates for the subject who died) - (weighted mean covariate
# vector at that time).  The weighted mean is defined over the subjects
# still at risk, with exp(X beta) as the weight.

events <- fit$y[,2]==1
etime  <- fit$y[events,1]   #the event times --- may have duplicates
indx   <- match(etime, fitd$time)
schoen <- fit$x[events,] - fitd$means[indx,]
```

---

coxph.object *Proportional Hazards Regression Object*

---

## Description

This class of objects is returned by the coxph class of functions to represent a fitted proportional hazards model. Objects of this class have methods for the functions print, summary, residuals, predict and survfit.

## Arguments

| | |
|---|---|
| coefficients | the vector of coefficients. If the model is over-determined there will be missing values in the vector corresponding to the redundant columns in the model matrix. |
| var | the variance matrix of the coefficients. Rows and columns corresponding to any missing coefficients are set to zero. |
| naive.var | this component will be present only if the robust option was true. If so, the var component will contain the robust estimate of variance, and this component will contain the ordinary estimate. |
| loglik | a vector of length 2 containing the log-likelihood with the initial values and with the final values of the coefficients. |
| score | value of the efficient score test, at the initial value of the coefficients. |
| rscore | the robust log-rank statistic, if a robust variance was requested. |
| wald.test | the Wald test of whether the final coefficients differ from the initial values. |
| iter | number of iterations used. |
| linear.predictors | the vector of linear predictors, one per subject. Note that this vector has been centered, see predict.coxph for more details. |
| residuals | the martingale residuals. |
| means | vector of column means of the X matrix. Subsequent survival curves are adjusted to this value. |
| n | the number of observations used in the fit. |

| | |
|---|---|
| nevent | the number of events (usually deaths) used in the fit. |
| concordance | the concordance, as computed by survConcordance. |
| first | the first derivative vector at the solution. |
| weights | the vector of case weights, if one was used. |
| method | the computation method used. |
| na.action | the na.action attribute, if any, that was returned by the na.action routine. |
| | The object will also contain the following, for documentation see the lm object: terms, assign, formula, call, and, optionally, x, y, and/or frame. |

## Components

The following components must be included in a legitimate coxph object.

## See Also

coxph, coxph.detail, cox.zph, residuals.coxph, survfit, survreg.

---

coxph.wtest *Compute a quadratic form*

---

## Description

This function is used internally by several survival routines. It computes a simple quadratic form, while properly dealing with missings.

## Usage

```
coxph.wtest(var, b, toler.chol = 1e-09)
```

## Arguments

| | |
|---|---|
| var | variance matrix |
| b | vector |
| toler.chol | tolerance for the internal cholesky decomposition |

## Details

Compute b' V-inverse b. Equivalent to sum(b * solve(V,b)), except for the case of redundant covariates in the original model, which lead to NA values in V and b.

## Value

a real number

## Author(s)

Terry Therneau

dsurvreg *Distributions available in survreg.*

## Description

Density, cumulative distribution function, quantile function and random generation for the set of distributions supported by the survreg function.

## Usage

```
dsurvreg(x, mean, scale=1, distribution='weibull', parms)
psurvreg(q, mean, scale=1, distribution='weibull', parms)
qsurvreg(p, mean, scale=1, distribution='weibull', parms)
rsurvreg(n, mean, scale=1, distribution='weibull', parms)
```

## Arguments

| | |
|---|---|
| x | vector of quantiles. Missing values (NAs) are allowed. |
| q | vector of quantiles. Missing values (NAs) are allowed. |
| p | vector of probabilities. Missing values (NAs) are allowed. |
| n | number of random deviates to produce |
| mean | vector of linear predictors for the model. This is replicated to be the same length as p, q or n. |
| scale | vector of (positive) scale factors. This is replicated to be the same length as p, q or n. |
| distribution | character string giving the name of the distribution. This must be one of the elements of survreg.distributions |
| parms | optional parameters, if any, of the distribution. For the t-distribution this is the degrees of freedom. |

## Details

Elements of q or p that are missing will cause the corresponding elements of the result to be missing.

The location and scale values are as they would be for survreg. The label "mean" was an unfortunate choice (made in mimicry of qnorm); since almost none of these distributions are symmetric it will not actually be a mean, but corresponds instead to the linear predictor of a fitted model. Translation to the usual parameterization found in a textbook is not always obvious. For example, the Weibull distribution is fit using the Extreme value distribution along with a log transformation. Letting $F(t) = 1 - \exp[-(at)^p]$ be the cumulative distribution of the Weibull using a standard parameterization in terms of $a$ and $p$, the survreg location corresponds to $-\log(a)$ and the scale to $1/p$ (Kalbfleisch and Prentice, section 2.2.2).

## Value

density (dsurvreg), probability (psurvreg), quantile (qsurvreg), or for the requested distribution with mean and scale parameters mean and sd.

## References

haz <- dsurvreg(x, 2, 3)/ (1-psurvreg(x, 2, 3))
## Not run:
plot(x, haz, log='xy', ylab="Hazard") #line with slope (1/scale -1)

## End(Not run)
```

---

finegray *Create data for a Fine-Gray model*

---

## Description

The Fine-Gray model can be fit by first creating a special data set, and then fitting a weighted Cox model to the result. This routine creates the data set.

## Usage

```
finegray(formula, data, subset, na.action= na.pass, etype,
    prefix="fg", count, id, timefix=TRUE)
```

## Arguments

| | |
|---|---|
| formula | a standard model formula, with survival on the left and covariates on the right. |
| data | an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. |
| subset | an optional vector specifying a subset of observations to be used in the fitting process. |
| na.action | a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options. |

| | |
|---|---|
| `etype` | the event type for which a data set will be generated. The default is to use whichever is listed first in the multi-state survival object. |
| `prefix` | the routine will add 4 variables to the data set: a start and end time for each interval, status, and a weight for the interval. The default names of these are "fgstart", "fgstop", "fgstatus", and "fgwt"; the `prefix` argument determines the initial portion of the new names. |
| `count` | a variable name in the output data set for an optional variable that will contain the the replication count for each row of the input data. If a row is expanded into multiple lines it will contain 1, 2, etc. |
| `id` | optional, the variable name in the data set which identifies subjects. |
| `timefix` | process times through the `aeqSurv` function to eliminate potential roundoff issues. |

## Details

The function expects a multi-state survival expression or variable as the left hand side of the formula, e.g. `Surv(atime, astat)` where `astat` is a factor whose first level represents censoring and remaining levels are states. The output data set will contain simple survival data (status = 0 or 1) for a single endpoint of interest. In the output data set subjects who did not experience the event of interest become censored subjects whose times are artificially extended over multiple intervals, with a decreasing case weight from interval to interval. The output data set will normally contain many more rows than the input.

Time dependent covariates are allowed, but not (currently) delayed entry. If there are time dependent covariates, e.g.., the input data set had `Surv(entry, exit, stat)` as the left hand side, then an `id` statement is required. The program does data checks in this case, and needs to know which rows belong to each subject.

See the competing risks vignette for more details.

## Value

a data frame

## Examples

```
# Treat time to death and plasma cell malignancy as competing risks
etime <- with(mgus2, ifelse(pstat==0, futime, ptime))
event <- with(mgus2, ifelse(pstat==0, 2*death, 1))
event <- factor(event, 0:2, labels=c("censor", "pcm", "death"))

# FG model for PCM
pdata <- finegray(Surv(etime, event) ~ ., data=mgus2)
fgfit <- coxph(Surv(fgstart, fgstop, fgstatus) ~ age + sex,
                     weight=fgwt, data=pdata)

# Compute the weights separately by sex
adata <- finegray(Surv(etime, event) ~ . + strata(sex),
             data=mgus2, na.action=na.pass)
```

---

`flchain` *Assay of serum free light chain for 7874 subjects.*

---

## Description

This is a stratified random sample containing 1/2 of the subjects from a study of the relationship between serum free light chain (FLC) and mortality. The original sample contains samples on approximately 2/3 of the residents of Olmsted County aged 50 or greater.

## Usage

```
data(flchain)
```

## Format

A data frame with 7874 persons containing the following variables.

`age` age in years

`sex` F=female, M=male

`sample.yr` the calendar year in which a blood sample was obtained

`kappa` serum free light chain, kappa portion

`lambda` serum free light chain, lambda portion

`flc.grp` the FLC group for the subject, as used in the original analysis

`creatinine` serum creatinine

`mgus` 1 if the subject had been diagnosed with monoclonal gammapothy (MGUS)

`futime` days from enrollment until death. Note that there are 3 subjects whose sample was obtained on their death date.

`death` 0=alive at last contact date, 1=dead

`chapter` for those who died, a grouping of their primary cause of death by chapter headings of the International Code of Diseases ICD-9

## Details

In 1995 Dr. Robert Kyle embarked on a study to determine the prevalence of monoclonal gammopathy of undetermined significance (MGUS) in Olmsted County, Minnesota, a condition which is normally only found by chance from a test (serum electrophoresis) which is ordered for other causes. Later work suggested that one component of immunoglobulin production, the serum free light chain, might be a possible marker for immune disregulation. In 2010 Dr. Angela Dispenzieri and colleagues assayed FLC levels on those samples from the original study for which they had patient permission and from which sufficient material remained for further testing. They found that elevated FLC levels were indeed associated with higher death rates.

Patients were recruited when they came to the clinic for other appointments, with a final random sample of those who had not yet had a visit since the study began. An interesting side question is whether there are differences between early, mid, and late recruits.

This data set contains an age and sex stratified random sample that includes 7874 of the original 15759 subjects. The original subject identifiers and dates have been removed to protect patient identity. Subsampling was done to further protect this information.

## Examples

```
data(flchain)
age.grp <-  cut(flchain$age, c(49,54, 59,64, 69,74,79, 89, 110),
               labels= paste(c(50,55,60,65,70,75,80,90),
                             c(54,59,64,69,74,79,89,109), sep='-'))
table(flchain$sex, age.grp)
```

---

`frailty` *Random effects terms*

---

## Description

The frailty function allows one to add a simple random effects term to a Cox or survreg model.

## Usage

```
frailty(x, distribution="gamma", ...)
frailty.gamma(x, sparse = (nclass > 5), theta, df, eps = 1e-05,
         method = c("em","aic", "df", "fixed"), ...)
frailty.gaussian(x, sparse = (nclass > 5), theta, df,
```

```
         method =c("reml","aic", "df", "fixed"), ...)
frailty.t(x, sparse = (nclass > 5), theta, df, eps = 1e-05, tdf = 5,
         method = c("aic", "df", "fixed"), ...)
```

## Arguments

| | |
|---|---|
| x | the variable to be entered as a random effect. It is always treated as a factor. |
| distribution | either the gamma, gaussian or t distribution may be specified. The routines frailty.gamma, frailty.gaussian and frailty.t do the actual work. |
| ... | Arguments for specific distribution, including (but not limited to) |
| sparse | cutoff for using a sparse coding of the data matrix. If the total number of levels of x is larger than this value, then a sparse matrix approximation is used. The correct cutoff is still a matter of exploration: if the number of levels is very large (thousands) then the non-sparse calculation may not be feasible in terms of both memory and compute time. Likewise, the accuracy of the sparse approximation appears to be related to the maximum proportion of subjects in any one class, being best when no one class has a large membership. |
| theta | if specified, this fixes the variance of the random effect. If not, the variance is a parameter, and a best solution is sought. Specifying this implies method='fixed'. |
| df | if specified, this fixes the degrees of freedom for the random effect. Specifying this implies method='df'. Only one of theta or df should be specified. |
| method | the method used to select a solution for theta, the variance of the random effect. The fixed corresponds to a user-specified value, and no iteration is done. The df selects the variance such that the degrees of freedom for the random effect matches a user specified value. The aic method seeks to maximize Akaike's information criteria 2*(partial likelihood - df). The em and reml methods are specific to Cox models with gamma and gaussian random effects, respectively. Please see further discussion below. |
| tdf | the degrees of freedom for the t-distribution. |
| eps | convergence criteria for the iteration on theta. |

## Details

The frailty plugs into the general penalized modeling framework provided by the coxph and survreg routines. This framework deals with likelihood, penalties, and degrees of freedom; these aspects work well with either parent routine.

Therneau, Grambsch, and Pankratz show how maximum likelihood estimation for the Cox model with a gamma frailty can be accomplished using a general penalized routine, and Ripatti and Palmgren work through a similar argument for the Cox model with a gaussian frailty. Both of these are specific to the Cox model. Use of gamma/ml or gaussian/reml with survreg does not lead to valid results.

The extensible structure of the penalized methods is such that the penalty function, such as frailty or pspine, is completely separate from the modeling routine. The strength of this is that a user can plug in any penalization routine they choose. A weakness is that it is very difficult for the modeling routine to know whether a sensible penalty routine has been supplied.

Note that use of a frailty term implies a mixed effects model and use of a cluster term implies a GEE approach; these cannot be mixed.

The coxme package has superseded this method. It is faster, more stable, and more flexible.

### Value

this function is used in the model statement of either `coxph` or `survreg`. It's results are used internally.

# Random institutional effect
coxph(Surv(time, status) ~ age + frailty(inst, df=4), lung)

# Litter effects for the rats data
rfit2a <- survreg(Surv(time, status) ~ rx +
                  frailty.gaussian(litter, df=13, sparse=FALSE), rats,
                  subset= (sex=='f'))
rfit2b <- survreg(Surv(time, status) ~ rx +
                  frailty.gaussian(litter, df=13, sparse=TRUE), rats,
                  subset= (sex=='f'))
```

---

## genfan *Generator fans*

---

### Description

The data come from a field engineering study of the time to failure of diesel generator fans. The ultimate goal was to decide whether or not to replace the working fans with a higher quality fan to prevent future failures. Seventy generators were studied. For each one, the number of hours of running time from its first being put into service until fan failure or until the end of the study(whichever came first) was recorded.

### Usage

```
data("genfan")
```

### Format

A data frame with 70 observations on the following 2 variables.

`hours` hours of service

`status` 1=failure, 0=censored

### References

Nelson, Journal of Quality Technology, 1:27-52, 1969

`heart` *Stanford Heart Transplant data*

## Description

Survival of patients on the waiting list for the Stanford heart transplant program.

## Usage

```
heart
jasa
jasa1
```

## Format

jasa: original data

| | |
|---|---|
| birth.dt: | birth date |
| accept.dt: | acceptance into program |
| tx.date: | transplant date |
| fu.date: | end of followup |
| fustat: | dead or alive |
| surgery: | prior bypass surgery |
| age: | age (in years) |
| futime: | followup time |
| wait.time: | time before transplant |
| transplant: | transplant indicator |
| mismatch: | mismatch score |

## is.ratetable — *Verify that an object is of class ratetable.*

### Description

The function verifies not only the `class` attribute, but the structure of the object.

### Usage

```
is.ratetable(x, verbose=FALSE)
```

### Arguments

| | |
|---|---|
| `x` | the object to be verified. |
| `verbose` | if `TRUE` and the object is not a ratetable, then return a character string describing the way(s) in which `x` fails to be a proper ratetable object. |

### Details

Rate tables are used by the `pyears` and `survexp` functions, and normally contain death rates for some population, categorized by age, sex, or other variables. They have a fairly rigid structure, and the `verbose` option can help in creating a new rate table.

### Value

returns `TRUE` if `x` is a ratetable, and `FALSE` or a description if it is not.

### See Also

`pyears`, `survexp`.

### Examples

```
is.ratetable(survexp.us)  # True
is.ratetable(cancer)      # False
```

## kidney — *Kidney catheter data*

### Description

Data on the recurrence times to infection, at the point of insertion of the catheter, for kidney patients using portable dialysis equipment. Catheters may be removed for reasons other than infection, in which case the observation is censored. Each patient has exactly 2 observations.

This data has often been used to illustrate the use of random effects (frailty) in a survival model. However, one of the males (id 21) is a large outlier, with much longer survival than his peers. If this observation is removed no evidence remains for a random subject effect.

### Format

| | |
|---|---|
| patient: | id |
| time: | time |
| status: | event status |
| age: | in years |
| sex: | 1=male, 2=female |
| disease: | disease type (0=GN, 1=AN, 2=PKD, 3=Other) |
| frail: | frailty estimate from original paper |

## Note

The original paper ignored the issue of tied times and so is not exactly reproduced by the survival package.

## Source

CA McGilchrist, CW Aisbett (1991), Regression with frailty in survival analysis. *Biometrics* **47**, 461–66.

## Examples

```
kfit <- coxph(Surv(time, status)~ age + sex + disease + frailty(id), kidney)
kfit0 <- coxph(Surv(time, status)~ age + sex + disease, kidney)
kfitm1 <- coxph(Surv(time,status) ~ age + sex + disease +
frailty(id, dist='gauss'), kidney)
```

---

`lines.survfit` *Add Lines or Points to a Survival Plot*

---

## Description

Often used to add the expected survival curve(s) to a Kaplan-Meier plot generated with `plot.survfit`.

## Usage

```
## S3 method for class 'survfit'
lines(x, type="s", mark=3, col=1, lty=1,
        lwd=1, cex=1, mark.time=FALSE,
xscale=1,  firstx=0, firsty=1, xmax, fun, conf.int=FALSE,
        conf.times, conf.cap=.005, conf.offset=.012,  ...)
## S3 method for class 'survexp'
lines(x, type="l", ...)
## S3 method for class 'survfit'
points(x, xscale, xmax, fun, censor=FALSE, col=1, pch,
...)
```

## Arguments

| | |
|---|---|
| x | a survival object, generated from the survfit or survexp functions. |
| type | the line type, as described in lines. The default is a step function for survfit objects, and a connected line for survexp objects. All other arguments for lines.survexp are identical to those for lines.survfit. |
| mark, col, lty, lwd, cex | vectors giving the mark symbol, color, line type, line width and character size for the added curves. Of this set only color is applicable to points. |
| pch | plotting characters for points, in the style of matplot, i.e., either a single string of characters of which the first will be used for the first curve, etc; or a vector of characters or integers, one element per curve. |
| censor | should censoring times be displayed for the points function? |
| ... | other graphical parameters |
| mark.time | controls the labeling of the curves. If FALSE, no labeling is done. If TRUE, then curves are marked at each censoring time. If mark.time is a numeric vector, then curves are marked at the specified time points. |
| xscale | this parameter is no longer necessary and is ignored. See the note in plot.survfit. |
| firstx, firsty | the starting point for the survival curves. If either of these is set to NA or < blank > the plot will start at the first time point of the curve. |
| xmax | the maximum horizontal plot coordinate. This shortens the curve before plotting it, so unlike using the xlim graphical parameter, warning messages about out of bounds points are not generated. |
| fun | an arbitrary function defining a transformation of the survival curve. For example fun=log is an alternative way to draw a log-survival curve (but with the axis labeled with log(S) values). Four often used transformations can be specified with a character argument instead: "log" is the same as using the log=T option, "event" plots cumulative events (f(y) = 1-y), "cumhaz" plots the cumulative hazard function (f(y) = -log(y)) and "cloglog" creates a complimentary log-log survival plot (f(y) = log(-log(y))) along with log scale for the x-axis. |
| conf.int | if TRUE, confidence bands for the curves are also plotted. If set to "only", then only the CI bands are plotted, and the curve itself is left off. This can be useful for fine control over the colors or line types of a plot. |
| conf.times | optional vector of times at which to place a confidence bar on the curve(s). If present, these will be used instead of confidence bands. |
| conf.cap | width of the horizontal cap on top of the confidence bars; only used if conf.times is used. A value of 1 is the width of the plot region. |
| conf.offset | the offset for confidence bars, when there are multiple curves on the plot. A value of 1 is the width of the plot region. If this is a single number then each curve's bars are offset by this amount from the prior curve's bars, if it is a vector the values are used directly. |

## Details

When the survfit function creates a multi-state survival curve the resulting object has class 'survfitms'. The only difference in the plots is that that it defaults to a curve that goes from lower left to upper right (starting at 0), where survival curves default to starting at 1 and going down. All other options are identical.

### Value

a list with components x and y, containing the coordinates of the last point on each of the curves (but not of the confidence limits). This may be useful for labeling.

### Side Effects

one or more curves are added to the current plot.

### See Also

lines, par, plot.survfit, survfit, survexp.

### Examples

```
fit <- survfit(Surv(time, status==2) ~ sex, pbc,subset=1:312)
plot(fit, mark.time=FALSE, xscale=365.25,
        xlab='Years', ylab='Survival')
lines(fit[1], lwd=2)    #darken the first curve and add marks

# Add expected survival curves for the two groups,
#   based on the US census data
# The data set does not have entry date, use the midpoint of the study
efit <- survexp(~ ratetable(sex=sex,age=age*365.35,year=as.Date('1979/1/1')) +
            sex, data=pbc,  times=(0:24)*182)

title(main="Primary Biliary Cirrhosis, Observed and Expected")
```

---

## logan — *Data from the 1972-78 GSS data used by Logan*

---

### Description

Intergenerational occupational mobility data with covariates.

### Usage

```
data(logan)
```

### Format

A data frame with 838 observations on the following 4 variables.

**occupation** subject's occupation, a factor with levels farm, operatives, craftsmen, sales, and professional

**focc** father's occupation

**education** total years of schooling, 0 to 20

**race** levels of non-black and black

## Source

General Social Survey data, see the web site for detailed information on the variables. http://www3.norc.org/GSS+Website.

---

`logLik.coxph` *logLik method for a Cox model*

---

## Description

The logLik function for survival models

## Usage

```
## S3 method for class 'coxph'
logLik(object, ...)
## S3 method for class 'survreg'
logLik(object, ...)
```

## Arguments

| | |
|---|---|
| `object` | the result of a `coxph` or `survreg` fit |
| `...` | optional arguments for other instances of the method |

## Details

The logLik function is used by summary functions in R such as `AIC`. For a Cox model, this method returns the partial likelihood. The number of degrees of freedom (df) used by the fit and the effective number of observations (nobs) are added as attributes. Per Raftery and others, the effective number of observations is the taken to be the number of events in the data set.

For a `survreg` model the proper value for the effective number of observations is still an open question (at least to this author). For right censored data the approach of `logLik.coxph` is the possible the most sensible, but for interval censored observations the result is unclear. The code currently does not add a *nobs* attribute.

## Value

an object of class `logLik`

## Author(s)

Terry Therneau

`mgus` *Monoclonal gammapothy data*

## Description

Natural history of 241 subjects with monoclonal gammapothy of undetermined significance (MGUS).

## Usage

```
mgus
mgus1
```

## Format

mgus: A data frame with 241 observations on the following 12 variables.

| | |
|---|---|
| id: | subject id |
| age: | age in years at the detection of MGUS |
| sex: | `male` or `female` |
| dxyr: | year of diagnosis |
| pcdx: | for subjects who progress to a plasma cell malignancy the subtype of malignancy: multiple myeloma (MM) is the most common, followed by amyloidosis (AM), macroglobulinemia (MA), and other lymphprolifative disorders (LP) |
| pctime: | days from MGUS until diagnosis of a plasma cell malignancy |
| futime: | days from diagnosis to last follow-up |
| death: | 1= follow-up is until death |
| alb: | albumin level at MGUS diagnosis |
| creat: | creatinine at MGUS diagnosis |
| hgb: | hemoglobin at MGUS diagnosis |
| mspike: | size of the monoclonal protein spike at diagnosis |

mgus1: The same data set in start,stop format. Contains the id, age, sex, and laboratory variable described above along with

| | |
|---|---|
| start, stop: | sequential intervals of time for each subject |
| status: | =1 if the interval ends in an event |
| event: | a factor containing the event type: censor, death, or plasma cell malignancy |
| enum: | event number for each subject: 1 or 2 |

## Details

Plasma cells are responsible for manufacturing immunoglobulins, an important part of the immune defense. At any given time there are estimated to be about $10^6$ different immunoglobulins in the circulation at any one time. When a patient has a plasma cell malignancy the distribution will become dominated by a single isotype, the product of the malignant clone, visible as a spike on a serum protein electrophoresis. Monoclonal gammapothy of undertermined significance (MGUS) is the presence of such a spike, but in a patient with no evidence of overt malignancy. This data set of 241 sequential subjects at Mayo Clinic was the groundbreaking study defining the natural

history of such subjects. Due to the diligence of the principle investigator 0 subjects have been lost to follow-up.

Three subjects had MGUS detected on the day of death. In data set `mgus1` these subjects have the time to MGUS coded as .5 day before the death in order to avoid tied times.

These data sets were updated in Jan 2015 to correct some small errors.

## Examples

```
# Create the competing risk curves for time to first of death or PCM
sfit <- survfit(Surv(start, stop, event) ~ sex, mgus1, subset=(enum==1))
print(sfit)  # the order of printout is the order in which they plot

plot(sfit, xscale=365.25, lty=c(2,1,2,1), col=c(1,1,2,2),
     xlab="Years after MGUS detection", ylab="Proportion")
legend(0, .8, c("Death/male", "Death/female", "PCM/male", "PCM/female"),
       lty=c(1,1,2,2), col=c(2,1,2,1), bty='n')

title("Curves for the first of plasma cell malignancy or death")
# The plot shows that males have a higher death rate than females (no
# surprise) but their rates of conversion to PCM are essentially the same.
```

---

`mgus2` *Monoclonal gammapothy data*

---

## Description

Natural history of 1341 sequential patients with monoclonal gammapothy of undetermined significance (MGUS).

## Usage

```
data("mgus2")
```

## Format

A data frame with 1384 observations on the following 10 variables.

`id` subject identifier

`age` age at diagnosis, in years

`sex` a factor with levels `F` `M`

`hgb` hemoglobin

`creat` creatinine

`mspike` size of the monoclonal serum splike

`ptime` time until progression to a plasma cell malignancy (PCM) or last contact, in months

`pstat` occurrence of PCM: 0=no, 1=yes

`futime` time until death or last contact, in months

`death` occurrence of death: 0=no, 1=yes

## Details

This is a larger follow-on study of the condition also found in data set `mgus`.

## Source

Mayo Clinic data courtesy of Dr. Robert Kyle. All patient identifiers have been removed, age rounded to the nearest year, and follow-up times rounded to the nearest month.

## References

---

# `model.frame.coxph` *Model.frame method for coxph objects*

---

## Description

Recreate the model frame of a coxph fit.

## Usage

```
## S3 method for class 'coxph'
model.frame(formula, ...)
```

## Arguments

| | |
|---|---|
| `formula` | the result of a `coxph` fit |
| `...` | other arguments to `model.frame` |

## Details

For details, see the manual page for the generic function. This function would rarely be called by a user, it is mostly used inside functions like `residual` that need to recreate the data set from a model in order to do further calculations.

## Value

the model frame used in the original fit, or a parallel one for new data.

## Author(s)

Terry Therneau

## See Also

model.frame

---

model.matrix.coxph *Model.matrix method for coxph models*

---

## Description

Reconstruct the model matrix for a cox model.

## Usage

```
## S3 method for class 'coxph'
model.matrix(object, data=NULL, contrast.arg =
 object$contrasts, ...)
```

## Arguments

| | |
|---|---|
| object | the result of a coxph model |
| data | optional, a data frame from which to obtain the data |
| contrast.arg | optional, a contrasts object describing how factors should be coded |
| ... | other possible argument to model.frame |

## Details

When there is a data argument this function differs from most of the other model.matrix methods in that the response variable for the original formula is *not* required to be in the data.

If the data frame contains a terms attribute then it is assumed to be the result of a call to model.frame, otherwise a call to model.frame is applied with the data as an argument.

## Value

The model matrix for the fit

## Author(s)

Terry Therneau

## See Also

model.matrix

## Examples

```
fit1 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung)
xfit <- model.matrix(fit1)

fit2 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung,
                                 x=TRUE)
all.equal(model.matrix(fit1), fit2$x)
```

## myeloid — *Acute myeloid leukemia*

### Description

This simulated data set is based on a trial in acute myeloid leukemia.

### Format

A data frame with 646 observations on the following 9 variables.

`id` subject identifier, 1-646

`trt` treatment arm A or B

`futime` time to death or last follow-up

`death` 1 if `futime` is a death, 0 for censoring

`txtime` time to hematropetic stem cell transplant

`crtime` time to complete response

`rltime` time to relapse of disease

### Details

This data set is used to illustrate multi-state survival curves. The correlation between within-subject event times strongly resembles that from an actual trial, but none of the actual data values are from that source.

### Examples

```
coxph(Surv(futime, death) ~ trt, data=myeloid)
# See the mstate vignette for a more complete analysis
```

## neardate — *Find the index of the closest value in data set 2, for each entry in data set one.*

### Description

A common task in medical work is to find the closest lab value to some index date, for each subject.

### Usage

```
neardate(id1, id2, y1, y2, best = c("after", "prior"),
nomatch = NA_integer_)
```

## Arguments

| | |
|---|---|
| id1 | vector of subject identifiers for the index group |
| id2 | vector of identifiers for the reference group |
| y1 | normally a vector of dates for the index group, but any orderable data type is allowed |
| y2 | reference set of dates |
| best | if best='prior' find the index of the first y2 value less than or equal to the target y1 value, for each subject. If best='after' find the first y2 value which is greater than or equal to the target y1 value, for each subject. |
| nomatch | the value to return for items without a match |

## Details

This routine is closely related to match and to findInterval, the first of which finds exact matches and the second closest matches. This finds the closest matching date within sets of exactly matching identifiers. Closest date matching is often needed in clinical studies. For example data set 1 might contain the subject identifier and the date of some procedure and data set set 2 has the dates and values for laboratory tests, and the query is to find the first test value after the intervention but no closer than 7 days.

The id1 and id2 arguments are similar to match in that we are searching for instances of id1 that will be found in id2, and the result is the same length as id1. However, instead of returning the first match with id2 this routine returns the one that best matches with respect to y1.

The y1 and y2 arguments need not be dates, the function works for any data type such that the expression c(y1, y2) gives a sensible, sortable result. Be careful about matching Date and DateTime values and the impact of time zones, however, see as.POSIXct. If y1 and y2 are not of the same class the user is on their own. Since there exist pairs of unmatched data types where the result could be sensible, the routine will in this case proceed under the assumption that "the user knows what they are doing". Caveat emptor.

## Value

the index of the matching observations in the second data set, or the nomatch value for no successful match

## Author(s)

Terry Therneau

## See Also

match, findInterval

## Examples

```
data1 <- data.frame(id = 1:10,
                    entry.dt = as.Date(paste("2011", 1:10, "5", sep='-')))
temp1 <- c(1,4,5,1,3,6,9, 2,7,8,12,4,6,7,10,12,3)
data2 <- data.frame(id = c(1,1,1,2,2,4,4,5,5,5,6,8,8,9,10,10,12),
                    lab.dt = as.Date(paste("2011", temp1, "1", sep='-')),
                    chol = round(runif(17, 130, 280)))
```

```
#first cholesterol on or after enrollment
indx1 <- neardate(data1$id, data2$id, data1$entry.dt, data2$lab.dt)
data2[indx1, "chol"]

# Closest one, either before or after.
#
indx2 <- neardate(data1$id, data2$id, data1$entry.dt, data2$lab.dt,
                  best="prior")
ifelse(is.na(indx1), indx2, # none after, take before
       ifelse(is.na(indx2), indx1, #none before
       ifelse(abs(data2$lab.dt[indx2]- data1$entry.dt) <
              abs(data2$lab.dt[indx1]- data1$entry.dt), indx2, indx1)))

# closest date before or after, but no more than 21 days prior to index
indx2 <- ifelse((data1$entry.dt - data2$lab.dt[indx2]) >21, NA, indx2)
ifelse(is.na(indx1), indx2, # none after, take before
       ifelse(is.na(indx2), indx1, #none before
       ifelse(abs(data2$lab.dt[indx2]- data1$entry.dt) <
              abs(data2$lab.dt[indx1]- data1$entry.dt), indx2, indx1)))
```

---

`nwtco` *Data from the National Wilm's Tumor Study*

---

## Description

Measurement error example. Tumor histology predicts survival, but prediction is stronger with central lab histology than with the local institution determination.

## Usage

```
nwtco
```

## Format

A data frame with 4028 observations on the following 9 variables.

`seqno` id number

`instit` Histology from local institution

`histol` Histology from central lab

`stage` Disease stage

`study` study

`rel` indicator for relapse

`edrel` time to relapse

`age` age in months

`in.subcohort` Included in the subcohort for the example in the paper

---

pbc *Mayo Clinic Primary Biliary Cirrhosis Data*

---

## Description

D This data is from the Mayo Clinic trial in primary biliary cirrhosis (PBC) of the liver conducted between 1974 and 1984. A total of 424 PBC patients, referred to Mayo Clinic during that ten-year interval, met eligibility criteria for the randomized placebo controlled trial of the drug D-penicillamine. The first 312 cases in the data set participated in the randomized trial and contain

largely complete data. The additional 112 cases did not participate in the clinical trial, but consented to have basic measurements recorded and to be followed for survival. Six of those cases were lost to follow-up shortly after diagnosis, so the data here are on an additional 106 cases as well as the 312 randomized participants.

A nearly identical data set found in appendix D of Fleming and Harrington; this version has fewer missing values.

## Usage

```
pbc
```

## Format

| | |
|---|---|
| age: | in years |
| albumin: | serum albumin (g/dl) |
| alk.phos: | alkaline phosphotase (U/liter) |
| ascites: | presence of ascites |
| ast: | aspartate aminotransferase, once called SGOT (U/ml) |
| bili: | serum bilirunbin (mg/dl) |
| chol: | serum cholesterol (mg/dl) |
| copper: | urine copper (ug/day) |
| edema: | 0 no edema, 0.5 untreated or successfully treated |
| | 1 edema despite diuretic therapy |
| hepato: | presence of hepatomegaly or enlarged liver |
| id: | case number |
| platelet: | platelet count |
| protime: | standardised blood clotting time |
| sex: | m/f |
| spiders: | blood vessel malformations in the skin |
| stage: | histologic stage of disease (needs biopsy) |
| status: | status at endpoint, 0/1/2 for censored, transplant, dead |
| time: | number of days between registration and the earlier of death, |
| | transplantion, or study analysis in July, 1986 |
| trt: | 1/2/NA for D-penicillmain, placebo, not randomised |
| trig: | triglycerides (mg/dl) |

---

pbcseq *Mayo Clinic Primary Biliary Cirrhosis, sequential data*

---

## Description

This data is a continuation of the PBC data set, and contains the follow-up laboratory data for each study patient. An analysis based on the data can be found in Murtagh, et. al.

The primary PBC data set contains only baseline measurements of the laboratory parameters. This data set contains multiple laboratory results, but only on the 312 randomized patients. Some baseline data values in this file differ from the original PBC file, for instance, the data errors in prothrombin time and age which were discovered after the original analysis (see Fleming and Harrington, figure 4.6.7).

One "feature" of the data deserves special comment. The last observation before death or liver transplant often has many more missing covariates than other data rows. The original clinical protocol for these patients specified visits at 6 months, 1 year, and annually thereafter. At these protocol visits lab values were obtained for a large pre-specified battery of tests. "Extra" visits, often undertaken because of worsening medical condition, did not necessarily have all this lab work. The missing values are thus potentially informative.

## Usage

```

```

---

## plot.aareg *Plot an aareg object.*

---

### Description

Plot the estimated coefficient function(s) from a fit of Aalen's additive regression model.

### Usage

```
## S3 method for class 'aareg'
plot(x, se=TRUE, maxtime, type='s', ...)
```

### Arguments

| | |
|---|---|
| x | the result of a call to the aareg function |
| se | if TRUE, standard error bands are included on the plot |
| maxtime | upper limit for the x-axis. |
| type | graphical parameter for the type of line, default is "steps". |
| ... | other graphical parameters such as line type, color, or axis labels. |

### Side Effects

A plot is produced on the current graphical device.

### References

Aalen, O.O. (1989). A linear regression model for the analysis of life times. Statistics in Medicine, 8:907-925.

aareg

---

`plot.cox.zph` *Graphical Test of Proportional Hazards*

---

## Description

Displays a graph of the scaled Schoenfeld residuals, along with a smooth curve.

## Usage

```
## S3 method for class 'cox.zph'
plot(x, resid=TRUE, se=TRUE, df=4, nsmo=40, var,
        xlab="Time", ylab, lty=1:2, col=1, lwd=1, ...)
```

## Arguments

| | |
|---|---|
| `x` | result of the `cox.zph` function. |
| `resid` | a logical value, if `TRUE` the residuals are included on the plot, as well as the smooth fit. |
| `se` | a logical value, if `TRUE`, confidence bands at two standard errors will be added. |
| `df` | the degrees of freedom for the fitted natural spline, `df=2` leads to a linear fit. |
| `nsmo` | number of points to use for the lines |
| `var` | the set of variables for which plots are desired. By default, plots are produced in turn for each variable of a model. Selection of a single variable allows other features to be added to the plot, e.g., a horizontal line at zero or a main title.<br>This has been superseded by a subscripting method; see the example below. |
| `xlab` | label for the x-axis of the plot |
| `ylab` | optional label for the y-axis of the plot. If missing a default label is provided. This can be a vector of labels. |
| `lty, col, lwd` | line type, color, and line width for the overlaid curve. Each of these can be vector of length 2, in which case the second element is used for the confidence interval. |
| `...` | additional graphical arguments passed to the `plot` function. |

## Side Effects

a plot is produced on the current graphics device.

## See Also

`coxph`, `cox.zph`.

## Examples

```
vfit <- coxph(Surv(time,status) ~ trt + factor(celltype) +
              karno + age, data=veteran, x=TRUE)
temp <- cox.zph(vfit)
plot(temp, var=5)      # Look at Karnofsy score, old way of doing plot
plot(temp[5])     # New way with subscripting
abline(0, 0, lty=3)
# Add the linear fit as well
abline(lm(temp$y[,5] ~ temp$x)$coefficients, lty=4, col=3)
title(main="VA Lung Study")
```

---

# plot.survfit *Plot method for* survfit *objects*

---

## Description

A plot of survival curves is produced, one curve for each strata. The log=T option does extra work to avoid log(0), and to try to create a pleasing result. If there are zeros, they are plotted by default at 0.8 times the smallest non-zero value on the curve(s).

Curves are plotted in the same order as they are listed by print (which gives a 1 line summary of each). This will be the order in which col, lty, etc are used.

## Usage

```
## S3 method for class 'survfit'
plot(x, conf.int=, mark.time=FALSE,
 mark=3, col=1, lty=1, lwd=1, cex=1, log=FALSE, xscale=1, yscale=1,
 firstx=0, firsty=1, xmax, ymin=0, fun,
 xlab="", ylab="", xaxs="S",  conf.times, conf.cap=.005,
 conf.offset=.012, ...)
```

## Arguments

| | |
|---|---|
| x | an object of class survfit, usually returned by the survfit function. |
| conf.int | determines whether confidence intervals will be plotted. The default is to do so if there is only 1 curve, i.e., no strata. |
| mark.time | controls the labeling of the curves. If set to FALSE, no labeling is done. If TRUE, then curves are marked at each censoring time which is not also a death time. If mark.time is a numeric vector, then curves are marked at the specified time points. |
| mark | vector of mark parameters, which will be used to label the curves. The lines help file contains examples of the possible marks. The vector is reused cyclically if it is shorter than the number of curves. If it is present this implies mark.time = TRUE. |
| col | a vector of integers specifying colors for each curve. The default value is 1. |
| lty | a vector of integers specifying line types for each curve. The default value is 1. |
| lwd | a vector of numeric values for line widths. The default value is 1. |
| cex | a numeric value specifying the size of the marks. This is not treated as a vector; all marks have the same size. |

`log` a logical value, if TRUE the y axis wll be on a log scale. Alternately, one of the standard character strings "x", "y", or "xy" can be given to specific logarithmic horizontal and/or vertical axes.

`yscale` a numeric value used to multiply the labels on the y axis. A value of 100, for instance, would be used to give a percent scale. Only the labels are changed, not the actual plot coordinates, so that adding a curve with "`lines(surv.exp(...))`", say, will perform as it did without the `yscale` argument.

`xscale` a numeric value used like `yscale` for labels on the x axis. A value of 365.25 will give labels in years instead of the original days.

`firstx, firsty` the starting point for the survival curves. If either of these is set to `NA` the plot will start at the first time point of the curve. By default, the plot program obeys tradition by having the plot start at (0,0).

If `start.time` argument is used in `survfit`, `firstx` is set to that value.

`xmax` the maximum horizontal plot coordinate. This can be used to shrink the range of a plot. It shortens the curve before plotting it, so that unlike using the `xlim` graphical parameter, warning messages about out of bounds points are not generated.

`ymin` lower boundary for y values. Survival curves are most often drawn in the range of 0-1, even if none of the curves approach zero. The parameter is ignored if the `fun` argument is present, or if it has been set to `NA`.

`fun` an arbitrary function defining a transformation of the survival curve. For example `fun=log` is an alternative way to draw a log-survival curve (but with the axis labeled with log(S) values), and `fun=sqrt` would generate a curve on square root scale. Four often used transformations can be specified with a character argument instead: `"log"` is the same as using the `log=T` option, `"event"` plots cumulative events (f(y) = 1-y), `"cumhaz"` plots the cumulative hazard function (f(y) = -log(y)), and `"cloglog"` creates a complimentary log-log survival plot (f(y) = log(-log(y)) along with log scale for the x-axis).

`xlab` label given to the x-axis.

`ylab` label given to the y-axis.

`xaxs` either `"S"` for a survival curve or a standard x axis style as listed in `par`. Survival curves are usually displayed with the curve touching the y-axis, but not touching the bounding box of the plot on the other 3 sides. Type `"S"` accomplishes this by manipulating the plot range and then using the `"i"` style internally.

`conf.times` optional vector of times at which to place a confidence bar on the curve(s). If present, these will be used instead of confidence bands.

`conf.cap` width of the horizontal cap on top of the confidence bars; only used if conf.times is used. A value of 1 is the width of the plot region.

`conf.offset` the offset for confidence bars, when there are multiple curves on the plot. A value of 1 is the width of the plot region. If this is a single number then each curve's bars are offset by this amount from the prior curve's bars, if it is a vector the values are used directly.

`...` for future methods

## Details

When the `survfit` function creates a multi-state survival curve the resulting object also has class 'survfitms'. Competing risk curves are a common case. The only difference in the plots is that

multi-state defaults to a curve that goes from lower left to upper right (starting at 0), where survival curves by default start at 1 and go down. All other options are identical.

When the `conf.times` argument is used, the confidence bars are offset by `conf.offset` units to avoid overlap. The bar on each curve are the confidence interval for the time point at which the bar is drawn, i.e., different time points for each curve. If curves are steep at that point, the visual impact can sometimes substantially differ for positive and negative values of `conf.offset`.

## Value

a list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not the confidence limits). This may be useful for labeling.

## Note

In prior versions the behavior of `xscale` and `yscale` differed: the first changed the scale both for the plot and for all subsequent actions such as adding a legend, whereas `yscale` affected only the axis label. This was normalized in version 2-36.4, and both parameters now only affect the labeling.

## Examples

```
leukemia.surv <- survfit(Surv(time, status) ~ x, data = aml)
plot(leukemia.surv, lty = 2:3)
legend(100, .9, c("Maintenance", "No Maintenance"), lty = 2:3)
title("Kaplan-Meier Curves\nfor AML Maintenance Study")
lsurv2 <- survfit(Surv(time, status) ~ x, aml, type='fleming')
plot(lsurv2, lty=2:3, fun="cumhaz",
xlab="Months", ylab="Cumulative Hazard")
```

---

`predict.coxph` *Predictions for a Cox model*

---

## Description

Compute fitted values and regression terms for a model fitted by `coxph`

## Usage

```
## S3 method for class 'coxph'
predict(object, newdata,
type=c("lp", "risk", "expected", "terms", "survival"),
se.fit=FALSE, na.action=na.pass, terms=names(object$assign), collapse,
reference=c("strata", "sample"),  ...)
```

### Arguments

| | |
|---|---|
| `object` | the results of a coxph fit. |
| `newdata` | Optional new data at which to do predictions. If absent predictions are for the data frame used in the original fit. When coxph has been called with a formula argument created in another context, i.e., coxph has been called within another function and the formula was passed as an argument to that function, there can be problems finding the data set. See the note below. |
| `type` | the type of predicted value. Choices are the linear predictor (`"lp"`), the risk score exp(lp) (`"risk"`), the expected number of events given the covariates and follow-up time (`"expected"`), and the terms of the linear predictor (`"terms"`). The survival probability for a subject is equal to exp(-expected). |
| `se.fit` | if TRUE, pointwise standard errors are produced for the predictions. |
| `na.action` | applies only when the `newdata` argument is present, and defines the missing value action for the new data. The default is to include all observations. When there is no newdata, then the behavior of missing is dictated by the na.action option of the original fit. |
| `terms` | if type="terms", this argument can be used to specify which terms should be included; the default is all. |
| `collapse` | optional vector of subject identifiers. If specified, the output will contain one entry per subject rather than one entry per observation. |
| `reference` | reference for centering predictions, see details below |
| `...` | For future methods |

### Details

The Cox model is a *relative* risk model; predictions of type "linear predictor", "risk", and "terms" are all relative to the sample from which they came. By default, the reference value for each of these is the mean covariate within strata. The primary underlying reason is statistical: a Cox model only predicts relative risks between pairs of subjects within the same strata, and hence the addition of a constant to any covariate, either overall or only within a particular stratum, has no effect on the fitted results. Using the `reference="strata"` option causes this to be true for predictions as well.

When the results of `predict` are used in further calculations it may be desirable to use a fixed reference level. Use of `reference="sample"` will use the overall means, and agrees with the `linear.predictors` component of the coxph object (which uses the overall mean for backwards compatability with older code). Predictions of `type="terms"` are almost invariably passed forward to further calculation, so for these we default to using the sample as the reference.

Predictions of type "expected" incorporate the baseline hazard and are thus absolute instead of relative; the `reference` option has no effect on these.

Models that contain a `frailty` term are a special case: due to the technical difficulty, when there is a `newdata` argument the predictions will always be for a random effect of zero.

### Value

a vector or matrix of predictions, or a list containing the predictions (element "fit") and their standard errors (element "se.fit") if the se.fit option is TRUE.

## Note

Some predictions can be obtained directly from the coxph object, and for others it is necessary for the routine to have the entirety of the original data set, e.g., for type = `terms` or if standard errors are requested. This extra information is saved in the coxph object if `model=TRUE`, if not the original data is reconstructed. If it is known that such residuals will be required overall execution will be slightly faster if the model information is saved.

In some cases the reconstruction can fail. The most common is when coxph has been called inside another function and the formula was passed as one of the arguments to that enclosing function. Another is when the data set has changed between the original call and the time of the prediction call. In each of these the simple solution is to add `model=TRUE` to the original coxph call.

## Examples

```
options(na.action=na.exclude) # retain NA in predictions
fit <- coxph(Surv(time, status) ~ age + ph.ecog + strata(inst), lung)
#lung data set has status coded as 1/2
mresid <- (lung$status-1) - predict(fit, type='expected') #Martingale resid
predict(fit,type="lp")
predict(fit,type="expected")
predict(fit,type="risk",se.fit=TRUE)
predict(fit,type="terms",se.fit=TRUE)
```

---

`predict.survreg` *Predicted Values for a 'survreg' Object*

---

## Description

Predicted values for a `survreg` object

## Usage

```
## S3 method for class 'survreg'
predict(object, newdata,
type=c("response", "link", "lp", "linear", "terms", "quantile",
"uquantile"),
 se.fit=FALSE, terms=NULL, p=c(0.1, 0.9), na.action=na.pass, ...)
```

## Arguments

| | |
|---|---|
| `object` | result of a model fit using the `survreg` function. |
| `newdata` | data for prediction. If absent predictions are for the subjects used in the original fit. |
| `type` | the type of predicted value. This can be on the original scale of the data (response), the linear predictor (`"linear"`, with `"lp"` as an allowed abbreviation), a predicted quantile on the original scale of the data (`"quantile"`), a quantile on the linear predictor scale (`"uquantile"`), or the matrix of terms for the linear predictor (`"terms"`). At this time `"link"` and linear predictor (`"lp"`) are identical. |

| | |
|---|---|
| se.fit | if TRUE, include the standard errors of the prediction in the result. |
| terms | subset of terms. The default for residual type "terms" is a matrix with one column for every term (excluding the intercept) in the model. |
| p | vector of percentiles. This is used only for quantile predictions. |
| na.action | applies only when the newdata argument is present, and defines the missing value action for the new data. The default is to include all observations. |
| ... | for future methods |

## Value

a vector or matrix of predicted values.

                        ptime$fit - 2*ptime$se.fit)/30.5, 1-pct,
        xlab="Months", ylab="Survival", type='l', lty=c(1,2,2), col=1)
```

---

print.aareg *Print an aareg object*

---

## Description

Print out a fit of Aalen's additive regression model

### Usage

```
## S3 method for class 'aareg'
print(x, maxtime, test=c("aalen", "nrisk"),scale=1,...)
```

### Arguments

| | |
|---|---|
| x | the result of a call to the aareg function |
| maxtime | the upper time point to be used in the test for non-zero slope |
| test | the weighting to be used in the test for non-zero slope. The default weights are based on the variance of each coefficient, as a function of time. The alternative weight is proportional to the number of subjects still at risk at each time point. |
| scale | scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10-4); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read. |
| ... | for future methods |

### Details

The estimated increments in the coefficient estimates can become quite unstable near the end of follow-up, due to the small number of observations still at risk in a data set. Thus, the test for slope will sometimes be more powerful if this last 'tail' is excluded.

### Value

the calling argument is returned.

### Side Effects

the results of the fit are displayed.

## print.summary.coxph *Print method for summary.coxph objects*

---

### Description

Produces a printed summary of a fitted coxph model

### Usage

```
## S3 method for class 'summary.coxph'
print(x, digits=max(getOption("digits") - 3, 3),
signif.stars = getOption("show.signif.stars"), ...)
```

### Arguments

| | |
|---|---|
| x | the result of a call to summary.coxph |
| digits | significant digits to print |
| signif.stars | Show stars to highlight small p-values |
| ... | For future methods |

---

## print.summary.survexp *Print Survexp Summary*

---

### Description

Prints the results of summary.survexp

### Usage

```
## S3 method for class 'summary.survexp'
print(x, digits = max(options()$digits - 4, 3), ...)
```

### Arguments

| | |
|---|---|
| x | an object of class summary.survexp. |
| digits | the number of digits to use in printing the result. |
| ... | for future methods |

### Value

x, with the invisible flag set to prevent further printing.

### Author(s)

Terry Therneau

## print.summary.survfit *Print Survfit Summary*

### Description

Prints the result of `summary.survfit`.

### Usage

```
## S3 method for class 'summary.survfit'
print(x, digits = max(options() $digits-4, 3), ...)
```

### Arguments

| | |
|---|---|
| `x` | an object of class `"summary.survfit"`, which is the result of the `summary.survfit` function. |
| `digits` | the number of digits to use in printing the numbers. |
| `...` | for future methods |

### Value

`x`, with the invisible flag set to prevent printing.

### Side Effects

prints the summary created by `summary.survfit`.

### See Also

`options`, `print`, `summary.survfit`.

## print.survfit *Print a Short Summary of a Survival Curve*

### Description

Print number of observations, number of events, the restricted mean survival and its standard error, and the median survival with confidence limits for the median.

### Usage

```
## S3 method for class 'survfit'
print(x, scale=1, digits = max(options()$digits - 4,3),
    print.rmean=getOption("survfit.print.rmean"),
    rmean = getOption('survfit.rmean'),...)
```

## Arguments

| | |
|---|---|
| x | the result of a call to the survfit function. |
| scale | a numeric value to rescale the survival time, e.g., if the input data to survfit were in days, scale=365 would scale the printout to years. |
| digits | Number of digits to print |
| print.rmean,rmean | Options for computation and display of the restricted mean. |
| ... | for future results |

## Details

The mean and its variance are based on a truncated estimator. That is, if the last observation(s) is not a death, then the survival curve estimate does not go to zero and the mean is undefined. There are four possible approaches to resolve this, which are selected by the rmean option. The first is to set the upper limit to a constant, e.g.,rmean=365. In this case the reported mean would be the expected number of days, out of the first 365, that would be experienced by each group. This is useful if interest focuses on a fixed period. Other options are "none" (no estimate), "common" and "individual". The "common" option uses the maximum time for all curves in the object as a common upper limit for the auc calculation. For the "individual"options the mean is computed as the area under each curve, over the range from 0 to the maximum observed time for that curve. Since the end point is random, values for different curves are not comparable and the printed standard errors are an underestimate as they do not take into account this random variation. This option is provided mainly for backwards compatability, as this estimate was the default (only) one in earlier releases of the code. Note that SAS (as of version 9.3) uses the integral up to the last *event* time of each individual curve; we consider this the worst of the choices and do not provide an option for that calculation.

The median and its confidence interval are defined by drawing a horizontal line at 0.5 on the plot of the survival curve and its confidence bands. The intersection of the line with the lower CI band defines the lower limit for the median's interval, and similarly for the upper band. If any of the intersections is not a point, then we use the smallest point of intersection, e.g., if the survival curve were exactly equal to 0.5 over an interval.

## Value

x, with the invisible flag set to prevent printing. (The default for all print functions in R is to return the object passed to them; print.survfit complies with this pattern. If you want to capture these printed results for further processing, see the table component of summary.survfit.)

## Side Effects

The number of observations, the number of events, the median survival with its confidence interval, and optionally the restricted mean survival (rmean) and its standard error, are printed. If there are multiple curves, there is one line of output for each.

pspline *Smoothing splines using a pspline basis*

## Description

Specifies a penalised spline basis for the predictor. This is done by fitting a comparatively small set of splines and penalising the integrated second derivative. Traditional smoothing splines use one basis per observation, but several authors have pointed out that the final results of the fit are indistinguishable for any number of basis functions greater than about 2-3 times the degrees of freedom. Eilers and Marx point out that if the basis functions are evenly spaced, this leads to significant computational simplification, they refer to the result as a p-spline.

## Usage

```
pspline(x, df=4, theta, nterm=2.5 * df, degree=3, eps=0.1, method,
   Boundary.knots=range(x), intercept=FALSE, penalty=TRUE, combine, ...)

psplineinverse(x)
```

## Arguments

| | |
|---|---|
| `x` | for psline: a covariate vector. The function does not apply to factor variables. For psplineinverse x will be the result of a pspline call. |
| `df` | the desired degrees of freedom. One of the arguments `df` or `theta`' must be given, but not both. If `df=0`, then the AIC = (loglik -df) is used to choose an "optimal" degrees of freedom. If AIC is chosen, then an optional argument 'caic=T' can be used to specify the corrected AIC of Hurvich et. al. |
| `theta` | roughness penalty for the fit. It is a monotone function of the degrees of freedom, with theta=1 corresponding to a linear fit and theta=0 to an unconstrained fit of nterm degrees of freedom. |
| `nterm` | number of splines in the basis |
| `degree` | degree of splines |
| `eps` | accuracy for `df` |
| `method` | the method for choosing the tuning parameter `theta`. If theta is given, then 'fixed' is assumed. If the degrees of freedom is given, then 'df' is assumed. If method='aic' then the degrees of freedom is chosen automatically using Akaike's information criterion. |
| `...` | optional arguments to the control function |
| `Boundary.knots` | the spline is linear beyond the boundary knots. These default to the range of the data. |
| `intercept` | if TRUE, the basis functions include the intercept. |
| `penalty` | if FALSE a large number of attributes having to do with penalized fits are excluded. This is useful to create a pspline basis matrix for other uses. |
| `combine` | an optional vector of increasing integers. If two adjacent values of `combine` are equal, then the corresponding coefficients of the fit are forced to be equal. This is useful for monotone fits, see the vignette for more details. |

## Value

Object of class `pspline`, `coxph.penalty` containing the spline basis, with the appropriate attributes to be recognized as a penalized term by the coxph or survreg functions.

For psplineinverse the original x vector is reconstructed.

---

`pyears` *Person Years*

---

## Description

This function computes the person-years of follow-up time contributed by a cohort of subjects, stratified into subgroups. It also computes the number of subjects who contribute to each cell of the output table, and optionally the number of events and/or expected number of events in each cell.

## Usage

```
pyears(formula, data, weights, subset, na.action,  rmap,
       ratetable, scale=365.25, expect=c('event', 'pyears'),
       model=FALSE, x=FALSE, y=FALSE, data.frame=FALSE)
```

## Arguments

`formula` a formula object. The response variable will be a vector of follow-up times for each subject, or a `Surv` object containing the survival time and an event indicator. The predictors consist of optional grouping variables separated by + operators (exactly as in `survfit`), time-dependent grouping variables such as age (specified with `tcut`), and optionally a `ratetable` term. This latter matches each subject to his/her expected cohort.

| | |
|---|---|
| data | a data frame in which to interpret the variables named in the formula, or in the subset and the weights argument. |
| weights | case weights. |
| subset | expression saying that only a subset of the rows of the data should be used in the fit. |
| na.action | a missing-data filter function, applied to the model.frame, after any subset argument has been used. Default is options()$na.action. |
| rmap | an optional list that maps data set names to the ratetable names. See the details section below. |
| ratetable | a table of event rates, such as survexp.uswhite. |
| scale | a scaling for the results. As most rate tables are in units/day, the default value of 365.25 causes the output to be reported in years. |
| expect | should the output table include the expected number of events, or the expected number of person-years of observation. This is only valid with a rate table. |
| data.frame | return a data frame rather than a set of arrays. |
| model, x, y | If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result. |

## Details

Because pyears may have several time variables, it is necessary that all of them be in the same units. For instance, in the call

```
py <- pyears(futime ~ rx, rmap=list(age=age, sex=sex, year=entry.dt),
                  ratetable=survexp.us)
```

the natural unit of the ratetable is hazard per day, it is important that futime, age and entry.dt all be in days. Given the wide range of possible inputs, it is difficult for the routine to do sanity checks of this aspect.

The ratetable being used may have different variable names than the user's data set, this is dealt with by the rmap argument. The rate table for the above calculation was survexp.us, a call to summary{survexp.us} reveals that it expects to have variables age = age in days, sex, and year = the date of study entry, we create them in the rmap line. The sex variable is not mapped, therefore the code assumes that it exists in mydata in the correct format. (Note: for factors such as sex, the program will match on any unique abbreviation, ignoring case.)

A special function tcut is needed to specify time-dependent cutpoints. For instance, assume that age is in years, and that the desired final arrays have as one of their margins the age groups 0-2, 2-10, 10-25, and 25+. A subject who enters the study at age 4 and remains under observation for 10 years will contribute follow-up time to both the 2-10 and 10-25 subsets. If cut(age, c(0,2,10,25,100)) were used in the formula, the subject would be classified according to his starting age only. The tcut function has the same arguments as cut, but produces a different output object which allows the pyears function to correctly track the subject.

The results of pyears are normally used as input to further calculations. The print routine, therefore, is designed to give only a summary of the table.

## Value

a list with components:

| | |
|---|---|
| pyears | an array containing the person-years of exposure. (Or other units, depending on the rate table and the scale). The dimension and dimnames of the array correspond to the variables on the right hand side of the model equation. |
| n | an array containing the number of subjects who contribute time to each cell of the pyears array. |
| event | an array containing the observed number of events. This will be present only if the response variable is a Surv object. |
| expected | an array containing the expected number of events (or person years if expect ="pyears"). This will be present only if there was a ratetable term. |
| data | if the data.frame option was set, a data frame containing the variables n, event, pyears and event that supplants the four arrays listed above, along with variables corresponding to each dimension. There will be one row for each cell in the arrays. |
| offtable | the number of person-years of exposure in the cohort that was not part of any cell in the pyears array. This is often useful as an error check; if there is a mismatch of units between two variables, nearly all the person years may be off table. |
| tcut | whether the call included any time-dependent cutpoints. |
| summary | a summary of the rate-table matching. This is also useful as an error check. |
| call | an image of the call to the function. |
| observations | the number of observations in the input data set, after any missings were removed. |
| na.action | the na.action attribute contributed by an na.action routine, if any. |

# Example #2  Create the hearta data frame:
```

```
hearta <- by(heart, heart$id,
             function(x)x[x$stop == max(x$stop),])
hearta <- do.call("rbind", hearta)
# Produce pyears table of death rates on the surgical arm
#  The first is by age at randomization, the second by current age
fit1 <- pyears(Surv(stop/365.25, event) ~ cut(age + 48, c(0,50,60,70,100)) +
       surgery, data = hearta, scale = 1)
fit2 <- pyears(Surv(stop/365.25, event) ~ tcut(age + 48, c(0,50,60,70,100)) +
       surgery, data = hearta, scale = 1)
fit1$event/fit1$pyears  #death rates on the surgery and non-surg arm

fit2$event/fit2$pyears  #death rates on the surgery and non-surg arm
```

---

`quantile.survfit` *Quantiles from a survfit object*

---

## Description

Retrieve quantiles and confidence intervals for them from a survfit object.

## Usage

```
## S3 method for class 'survfit'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
  tolerance= sqrt(.Machine$double.eps), ...)
## S3 method for class 'survfitms'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
  tolerance= sqrt(.Machine$double.eps), ...)
```

## Arguments

| | |
|---|---|
| `x` | a result of the survfit function |
| `probs` | numeric vector of probabilities with values in [0,1] |
| `conf.int` | should lower and upper confidence limits be returned? |
| `tolerance` | tolerance for checking that the survival curve exactly equals one of the quantiles |
| `...` | optional arguments for other methods |

## Details

The kth quantile for a survival curve S(t) is the location at which a horizontal line at height p= 1-k intersects the plot of S(t). Since S(t) is a step function, it is possible for the curve to have a horizontal segment at exactly 1-k, in which case the midpoint of the horizontal segment is returned. This mirrors the standard behavior of the median when data is uncensored. If the survival curve does not fall to 1-k, then that quantile is undefined.

In order to be consistent with other quantile functions, the argument `prob` of this function applies to the cumulative distribution function F(t) = 1-S(t).

Confidence limits for the values are based on the intersection of the horizontal line at 1-k with the upper and lower limits for the survival curve. Hence confidence limits use the same p-value as was in effect when the curve was created, and will differ depending on the `conf.type` option of `survfit`. If the survival curves have no confidence bands, confidence limits for the quantiles are not available.

When a horizontal segment of the survival curve exactly matches one of the requested quantiles the returned value will be the midpoint of the horizontal segment; this agrees with the usual definition of a median for uncensored data. Since the survival curve is computed as a series of products, however, there may be round off error. Assume for instance a sample of size 20 with no tied times and no censoring. The survival curve after the 10th death is (19/20)(18/19)(17/18) ... (10/11) = 10/20, but the computed result will not be exactly 0.5. Any horizontal segment whose absolute difference with a requested percentile is less than `tolerance` is considered to be an exact match.

## Value

The quantiles will be a vector if the `survfit` object contains only a single curve, otherwise it will be a matrix or array. In this case the last dimension will index the quantiles.

If confidence limits are requested, then result will be a list with components `quantile`, `lower`, and `upper`, otherwise it is the vector or matrix of quantiles.

## Examples

```
fit <- survfit(Surv(time, status) ~ ph.ecog, data=lung)
quantile(fit)

cfit <- coxph(Surv(time, status) ~ age + strata(ph.ecog), data=lung)
csurv<- survfit(cfit, newdata=data.frame(age=c(40, 60, 80)),
                  conf.type ="none")
temp <- quantile(csurv, 1:5/10)
temp[2,3,]  # quantiles for second level of ph.ecog, age=80
quantile(csurv[2,3], 1:5/10)  # quantiles of a single curve, same result
```

---

`ratetable` *Ratetable reference in formula*

---

## Description

This function matches variable names in data to those in a ratetable for `survexp`

## Usage

```
ratetable(...)
```

## Arguments

| | |
|---|---|
| `...` | tags matching dimensions of the ratetable and variables in the data frame (see example) |

### Value

A data frame

### See Also

survexp,survexp.us,is.ratetable

### Examples

```
fit <- survfit(Surv(time, status) ~ sex, pbc,subset=1:312)

# The data set does not have entry date, use the midpoint of the study
efit <- survexp(~ ratetable(sex=sex,age=age*365.35,year=as.Date('1979/1/1')) +
            sex, data=pbc,  times=(0:24)*182)
## Not run:
plot(fit, mark.time=F, xscale=365.25, xlab="Years post diagnosis",
        ylab="Survival")
lines(efit, col=2) # Add the expected survival line

## End(Not run)
```

---

## ratetableDate — *Convert date objects to ratetable form*

---

### Description

This method converts dates from various forms into the internal form used in ratetable objects.

### Usage

```
ratetableDate(x)
```

### Arguments

| | |
|---|---|
| x | a date. The function currently has methods for Date, date, POSIXt, timeDate, and chron objects. |

### Details

This function is useful for those who create new ratetables, but is normally invisible to users. It is used internally by the survexp and pyears functions to map the various date formats; if a new method is added then those routines will automatically be adapted to the new date type.

### Value

a numeric vector, the number of days since 1/1/1960.

### Author(s)

Terry Therneau

### See Also

pyears, survexp

## ratetables — *Census Data Sets for the Expected Survival and Person Years Functions*

### Description

Census data sets for the expected survival and person years functions.

### Details

**us** total United States population, by age and sex, 1940 to 2004.

**usr** United States population, by age, sex and race, 1940 to 2004. Race is white, nonwhite, or black. For 1960 and 1970 the black population values were not reported separately, so the nonwhite values were used.

**mn** total Minnesota population, by age and sex, 1970 to 2004.

Each of these tables contains the daily hazard rate for a matched subject from the population, defined as $-\log(1-q)/365.25$ where $q$ is the 1 year probability of death as reported in the original tables. For age 25 in 1970, for instance, $p = 1 - q$ is is the probability that a subject who becomes 25 years of age in 1970 will achieve his/her 26th birthday. The tables are recast in terms of hazard per day entirely for computational convenience.

Each table is stored as an array, with additional attributes, and can be subset and manipulated as standard R arrays.

### Examples

```
survexp.uswhite <- survexp.usr[,,"white",]
```

## rats — *Rat treatment data from Mantel et al*

### Description

Rat treatment data from Mantel et al. Three rats were chosen from each of 100 litters, one of which was treated with a drug, and then all followed for tumor incidence.

### Usage

```
rats
```

### Format

| | |
|---|---|
| litter: | litter number from 1 to 100 |
| rx: | treatment,(1=drug, 0=control) |
| time: | time to tumor or last follow-up |
| status: | event status, 1=tumor and 0=censored |
| sex: | male or female |

## Note

Since only 2/150 of the male rats have a tumor, most analyses use only females (odd numbered litters), e.g. Lee et al.

## Source

N. Mantel, N. R. Bohidar and J. L. Ciminera. Mantel-Haenszel analyses of litter-matched time to response data, with modifications for recovery of interlitter information. Cancer Research, 37:3863-3868, 1977.

---

`rats2` *Rat data from Gail et al.*

---

## Description

48 rats were injected with a carcinogen, and then randomized to either drug or placebo. The number of tumors ranges from 0 to 13; all rats were censored at 6 months after randomization.

## Usage

```
rats2
```

## Format

| | |
|---|---|
| rat: | id |
| trt: | treatment,(1=drug, 0=control) |
| observation: | within rat |
| start: | entry time |
| stop: | exit time |
| status: | event status, 1=tumor, 0=censored |

residuals.coxph *Calculate Residuals for a 'coxph' Fit*

## Description

Calculates martingale, deviance, score or Schoenfeld residuals for a Cox proportional hazards model.

## Usage

```
## S3 method for class 'coxph'
residuals(object,
       type=c("martingale", "deviance", "score", "schoenfeld",
      "dfbeta", "dfbetas", "scaledsch","partial"),
       collapse=FALSE, weighted=FALSE, ...)
## S3 method for class 'coxph.null'
residuals(object,
       type=c("martingale", "deviance","score","schoenfeld"),
       collapse=FALSE, weighted=FALSE, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class coxph, representing a fitted Cox regression model. Typically this is the output from the coxph function. |
| type | character string indicating the type of residual desired. Possible values are "martingale", "deviance", "score", "schoenfeld", "dfbeta"', "dfbetas", and "scaledsch". Only enough of the string to determine a unique match is required. |
| collapse | vector indicating which rows to collapse (sum) over. In time-dependent models more than one row data can pertain to a single individual. If there were 4 individuals represented by 3, 1, 2 and 4 rows of data respectively, then collapse=c(1,1,1, 2, 3,3, 4,4,4,4) could be used to obtain per subject rather than per observation residuals. |
| weighted | if TRUE and the model was fit with case weights, then the weighted residuals are returned. |
| ... | other unused arguments |

## Value

For martingale and deviance residuals, the returned object is a vector with one element for each subject (without collapse). For score residuals it is a matrix with one row per subject and one column per variable. The row order will match the input data for the original fit. For Schoenfeld residuals, the returned object is a matrix with one row for each event and one column per variable. The rows are ordered by time within strata, and an attribute strata is attached that contains the number of observations in each strata. The scaled Schoenfeld residuals are used in the cox.zph function.

The score residuals are each individual's contribution to the score vector. Two transformations of this are often more useful: dfbeta is the approximate change in the coefficient vector if that observation were dropped, and dfbetas is the approximate change in the coefficients, scaled by the standard error for the coefficients.

## NOTE

For deviance residuals, the status variable may need to be reconstructed. For score and Schoenfeld residuals, the X matrix will need to be reconstructed.

## See Also

coxph

## Examples

```
fit <- coxph(Surv(start, stop, event) ~ (age + surgery)* transplant,
             data=heart)
mresid <- resid(fit, collapse=heart$id)
```

---

residuals.survreg *Compute Residuals for 'survreg' Objects*

---

## Description

This is a method for the function residuals for objects inheriting from class survreg.

## Usage

```
## S3 method for class 'survreg'
residuals(object, type=c("response", "deviance","dfbeta","dfbetas",
"working","ldcase","ldresp","ldshape", "matrix"), rsigma=TRUE,
collapse=FALSE, weighted=FALSE, ...)
```

## Arguments

| | |
|---|---|
| object | an object inheriting from class survreg. |
| type | type of residuals, with choices of "response", "deviance", "dfbeta", "dfbetas", "working", "ldcase", "lsresp", "ldshape", and "matrix". See the LaTeX documentation (survival/doc/survival.ps.gz) for more detail. |
| rsigma | include the scale parameters in the variance matrix, when doing computations. (I can think of no good reason not to). |
| collapse | optional vector of subject groups. If given, this must be of the same length as the residuals, and causes the result to be per group residuals. |
| weighted | give weighted residuals? Normally residuals are unweighted. |
| ... | other unused arguments |

## Value

A vector or matrix of residuals is returned. Response residuals are on the scale of the original data, working residuals are on the scale of the linear predictor, and deviance residuals are on log-likelihood scale. The dfbeta residuals are a matrix, where the ith row gives the approximate change in the coefficients due to the addition of subject i. The dfbetas matrix contains the dfbeta residuals, with each column scaled by the standard deviation of that coefficient.

The matrix type produces a matrix based on derivatives of the log-likelihood function. Let $L$ be the log-likelihood, $p$ be the linear predictor $X\beta$, and $s$ be $\log(\sigma)$. Then the 6 columns of the matrix are $L$, $dL/dp$,$\partial^2 L/\partial p^2$, $dL/ds$, $\partial^2 L/\partial s^2$ and $\partial^2 L/\partial p \partial s$. Diagnostics based on these quantities are discussed in an article by Escobar and Meeker. The main ones are the likelihood displacement residuals for perturbation of a case weight (`ldcase`), the response value (`ldresp`), and the `shape`.

rr  <- residuals(fit, type='matrix')
```

---

`retinopathy` *Diabetic Retinopathy*

---

## Description

A trial of laser coagulation as a treatment to delay diabetic retinopathy.

## Usage

```
data("retinopathy")
```

## Format

A data frame with 394 observations on the following 9 variables.

`id` numeric subject id

`laser` type of laser used: `xenon` `argon`

`eye` which eye was treated: `right` `left`

`age` age at diagnosis of diabetes

`type` type of diabetes: `juvenile` `adult`, (diagnosis before age 20)

`trt` 0 = control eye, 1 = treated eye

`futime` time to loss of vision or last follow-up

`status` 0 = censored, 1 = loss of vision in this eye

`risk` a risk score for the eye. This high risk subset is defined as a score of 6 or greater in at least one eye.

## Details

The 197 patients in this dataset were a 50% random sample of the patients with "high-risk" diabetic retinopathy as defined by the Diabetic Retinopathy Study (DRS). Each patient had one eye randomized to laser treatment and the other eye received no treatment, and has two observations in the data set. For each eye, the event of interest was the time from initiation of treatment to the time when visual acuity dropped below 5/200 two visits in a row. Thus there is a built-in lag time of approximately 6 months (visits were every 3 months). Survival times in this dataset are the actual time to vision loss in months, minus the minimum possible time to event (6.5 months). Censoring was caused by death, dropout, or end of the study.

## Examples

```
coxph(Surv(futime, status) ~ type + trt + cluster(id), retinopathy)
```

---

`rhDNase` *rhDNASE data set*

---

## Description

Results of a randomized trial of rhDNase for the treatment of cystic fibrosis.

## Format

A data frame with 767 observations on the following 8 variables.

`id` subject id

`inst` enrolling institution

`trt` treatment arm: 0=placebo, 1= rhDNase

`entry.dt` date of entry into the study

`end.dt` date of last follow-up

`fev` forced expriatory volume at enrollment, a measure of lung capacity

`ivstart` days from enrollment to the start of IV antibiotics

`ivstop` days from enrollment to the cessation of IV antibiotics

## Details

In patients with cystic fibrosis, extracellular DNA is released by leukocytes that accumulate in the airways in response to chronic bacterial infection. This excess DNA thickens the mucus, which then cannot be cleared from the lung by the cilia. The accumulation leads to exacerbations of respiratory symptoms and progressive deterioration of lung function. At the time of this study more than 90% of cystic fibrosis patients eventually died of lung disease.

Deoxyribonuclease I (DNase I) is a human enzyme normally present in the mucus of human lungs that digests extracellular DNA. Genentech, Inc. cloned a highly purified recombinant DNase I (rhDNase or Pulmozyme) which when delivered to the lungs in an aerosolized form cuts extracellular DNA, reducing the viscoelasticity of airway secretions and improving clearance. In 1992 the company conducted a randomized double-blind trial comparing rhDNase to placebo. Patients were then monitored for pulmonary exacerbations, along with measures of lung volume and flow. The primary endpoint was the time until first pulmonary exacerbation; however, data on all exacerbations were collected for 169 days.

The definition of an exacerbation was an infection that required the use of intravenous (IV) antibiotics. Subjects had 0–5 such episodes during the trial, those with more than one have multiple rows in the data set, those with none have NA for the IV start and end times. A few subjects were infected at the time of enrollment, subject 173 for instance has a first infection interval of -21 to 7. We do not count this first infection as an "event", and the subject first enters the risk set at day 7. Subjects who have an event are not considered to be at risk for another event during the course of antibiotics, nor for an additional 6 days after they end. (If the symptoms reappear immediately after cessation then from a medical standpoint this would not be a new infection.)

This data set reproduces the data in Therneau and Grambsch, is does not exactly reproduce those in Therneau and Hamilton due to data set updates.

## Examples

```
# Build the start-stop data set for analysis, and
#  replicate line 2 of table 8.13
first <- subset(rhDNase, !duplicated(id)) #first row for each subject
dnase <- tmerge(first, first, id=id, tstop=as.numeric(end.dt -entry.dt))

# Subjects whose fu ended during the 6 day window are the reason for
#  this next line
temp.end <- with(rhDNase, pmin(ivstop+6, end.dt-entry.dt))
dnase <- tmerge(dnase, rhDNase, id=id,
                      infect=event(ivstart),
                      end=  event(temp.end))
# toss out the non-at-risk intervals, and extra variables
#  3 subjects had an event on their last day of fu, infect=1 and end=1
dnase <- subset(dnase, (infect==1 | end==0), c(id:trt, fev:infect))
agfit <- coxph(Surv(tstart, tstop, infect) ~ trt + fev + cluster(id),
                 data=dnase)
```

---

`ridge` *Ridge regression*

---

## Description

When used in a coxph or survreg model formula, specifies a ridge regression term. The likelihood is penalised by `theta`/2 time the sum of squared coefficients. If `scale=T` the penalty is calculated for coefficients based on rescaling the predictors to have unit variance. If `df` is specified then `theta` is chosen based on an approximate degrees of freedom.

## Usage

```
ridge(..., theta, df=nvar/2, eps=0.1, scale=TRUE)
```

## Arguments

| | |
|---|---|
| `...` | predictors to be ridged |
| `theta` | penalty is `theta`/2 time sum of squared coefficients |
| `df` | Approximate degrees of freedom |
| `eps` | Accuracy required for `df` |
| `scale` | Scale variables before applying penalty? |

## Value

An object of class `coxph.penalty` containing the data and control functions.

lfit1 <- survreg(Surv(time, status) ~ age + ridge(ph.ecog, theta=5), cancer)
lfit2 <- survreg(Surv(time, status) ~ sex + ridge(age, ph.ecog, theta=1), cancer)
lfit3 <- survreg(Surv(time, status) ~ sex + age + ph.ecog, cancer)
```

## stanford2 — *More Stanford Heart Transplant data*

### Description

This contains the Stanford Heart Transplant data in a different format. The main data set is in heart.

### Usage

```
stanford2
```

### Format

| | |
|---|---|
| id: | ID number |
| time: | survival or censoring time |
| status: | censoring status |
| age: | in years |
| t5: | T5 mismatch score |

### Source

LA Escobar and WQ Meeker Jr (1992), Assessing influence in regression analysis with censored data. *Biometrics* **48**, 507–528. Page 519.

### See Also

predict.survreg, heart

## statefig — *Draw a state space figure.*

### Description

For multi-state survival models it is useful to have a figure that shows the states and the possible transitions between them. This function creates a simple "box and arrows" figure. It's goal was simplicity.

### Usage

```
statefig(layout, connect, margin = 0.03, box = TRUE, cex = 1, col = 1,
  lwd=1, lty=1, bcol=col, acol=col, alwd=lwd, alty=lty)
```

### Arguments

`layout` describes the layout of the boxes on the page. See the detailed description below.

`connect` a square matrix with one row for each state. If `connect[i,j] !=0` then an arrow is drawn from state i to state j. The row names of the matrix are used as the labels for the states.

`margin` the fraction of white space between the label and the surrounding box, and between the box and the arrows, as a function of the plot region size.

`box` should boxes be drawn? TRUE or FALSE.

`cex, col, lty, lwd` default graphical parameters used for the text and boxes. The last 3 can be a vector of values.

`bcol` color for the box, if it differs from that used for the text.

`acol, alwd, alty` color, line type and line width for the arrows. Only the first element is used.

### Details

The `layout` argument is normally a vector of integers, e.g., the vector (1, 3, 2) describes a layout with 3 columns. The first has a single state, the second column has 3 states and the third has 2. The coordinates of the plotting region are 0 to 1 for both x and y. Within a column the centers of the boxes are evenly spaced, with 1/2 a space between the boxes and the margin, e.g., 4 boxes would be at 1/8, 3/8, 5/8 and 7/8. If `layout` were a 1 column matrix with values of (1, 3, 2) then the layout will have three rows with 1, 3, and 2 boxes per row, respectively. Alternatively, the user can supply a 2 column matrix that directly gives the centers.

The values of the connect matrix should be 0 for pairs of states that do not have a transition and values between 0 and 2 for those that do. States are connected by an arc that passes through the centers of the two boxes and a third point that is between them. Specifically, consider a line segment joining the two centers and erect a second segment at right angles to the midpoint of length d times the distance from center to midpoint. The arc passes through this point. A value of d=0 gives a straight line, d=1 a right hand half circle centered on the midpoint and d= -1 a left hand half circle. The `connect` matrix contains values of d+1 with $-1 < d < 1$.

### Value

a matrix containing the centers of the boxes, with the invisible attribute set.

### Note

The goal of this function is to make "good enough" figures as simply as possible, and thereby to encourage users to draw them. The `layout` argument was inspired by the `diagram` package, which can draw more complex and well decorated figures, e.g., many different shapes, shading, multiple types of connecting lines, etc., but at the price of greater complexity.

### Author(s)

Terry Therneau

## Examples

```
# Draw a simple competing risks figure
states <- c("Entry", "Complete response", "Relapse", "Death")
connect <- matrix(0, 4, 4, dimnames=list(states, states))
connect[1, -1] <- c(1.1, 1, 0.9)
statefig(c(1, 3), connect)
```

---

strata *Identify Stratification Variables*

---

## Description

This is a special function used in the context of the Cox survival model. It identifies stratification variables when they appear on the right hand side of a formula.

## Usage

```
strata(..., na.group=FALSE, shortlabel, sep=', ')
```

## Arguments

| | |
|---|---|
| `...` | any number of variables. All must be the same length. |
| `na.group` | a logical variable, if `TRUE`, then missing values are treated as a distinct level of each variable. |
| `shortlabel` | if `TRUE` omit variable names from resulting factor labels. The default action is to omit the names if all of the arguments are factors, and none of them was named. |
| `sep` | the character used to separate groups, in the created label |

## Details

The result is identical to the `interaction` function, but for the labeling of the factors (`strata` is more verbose).

## Value

a new factor, whose levels are all possible combinations of the factors supplied as arguments.

## See Also

`coxph`, `interaction`

## Examples

```
a <- factor(rep(1:3,4), labels=c("low", "medium", "high"))
b <- factor(rep(1:4,3))

levels(strata(a,b,shortlabel=TRUE))

coxph(Surv(futime, fustat) ~ age + strata(rx), data=ovarian)
```

summary.aareg *Summarize an aareg fit*

## Description

Creates the overall test statistics for an Aalen additive regression model

## Usage

```
## S3 method for class 'aareg'
summary(object, maxtime, test=c("aalen", "nrisk"), scale=1,...)
```

## Arguments

| | |
|---|---|
| object | the result of a call to the aareg function |
| maxtime | truncate the input to the model at time "maxtime" |
| test | the relative time weights that will be used to compute the test |
| scale | scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10-4); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read. |
| ... | for future methods |

## Details

It is not uncommon for the very right-hand tail of the plot to have large outlying values, particularly for the standard error. The maxtime parameter can then be used to truncate the range so as to avoid these. This gives an updated value for the test statistics, without refitting the model.

The slope is based on a weighted linear regression to the cumulative coefficient plot, and may be a useful measure of the overall size of the effect. For instance when two models include a common variable, "age" for instance, this may help to assess how much the fit changed due to the other variables, in leiu of overlaying the two plots. (Of course the plots are often highly non-linear, so it is only a rough substitute). The slope is not directly related to the test statistic, as the latter is invariant to any monotone transformation of time.

## Value

a list is returned with the following components

| | |
|---|---|
| table | a matrix with rows for the intercept and each covariate, and columns giving a slope estimate, the test statistic, it's standard error, the z-score and a p-value |
| test | the time weighting used for computing the test statistics |
| test.statistic | the vector of test statistics |
| test.var | the model based variance matrix for the test statistic |
| test.var2 | optionally, a robust variance matrix for the test statistic |
| chisq | the overall test (ignoring the intercept term) for significance of any variable |
| n | a vector containing the number of observations, the number of unique death times used in the computation, and the total number of unique death times |

`summary.coxph` *Summary method for Cox models*

---

## Description

Produces a summary of a fitted coxph model

## Usage

```
## S3 method for class 'coxph'
summary(object, conf.int=0.95, scale=1,...)
```

## Arguments

| | |
|---|---|
| `object` | the result of a coxph fit |
| `conf.int` | level for computation of the confidence intervals. If set to FALSE no confidence intervals are printed |
| `scale` | vector of scale factors for the coefficients, defaults to 1. The confidence limits are for the risk change associated with one scale unit. |
| `...` | for future methods |

## Value

An object of class summary.coxph.

## See Also

```

---

summary.pyears *Summary function for pyears objecs*

---

## Description

Create a printable table of a person-years result.

## Usage

```
## S3 method for class 'pyears'
summary(object, header = TRUE, call = header, n = TRUE,
event = TRUE, pyears = TRUE, expected = TRUE, rate = FALSE, rr =expected,
ci.r = FALSE, ci.rr = FALSE, totals=FALSE, legend = TRUE, vline = FALSE,
vertical= TRUE, nastring=".", conf.level = 0.95,
scale = 1, ...)
```

## Arguments

| | |
|---|---|
| `object` | a pyears object |
| `header` | print out a header giving the total number of observations, events, person-years, and total time (if any) omitted from the table |
| `call` | print out a copy of the call |
| `n, event, pyears, expected` | logical arguments: should these elements be printed in the table? |
| `rate, ci.r` | logical arguments: should the incidence rate and/or its confidence interval be given in the table? |
| `rr, ci.rr` | logical arguments: should the hazard ratio and/or its confidence interval be given in the table? |
| `totals` | should row and column totals be added? |
| `legend` | should a legend be included in the printout? |
| `vline` | should vertical lines be included in the printed tables? |
| `vertical` | when there is only a single predictor, should the table be printed with the predictor on the left (vertical=TRUE) or across the top (vertical=FALSE)? |
| `nastring` | what to use for missing values in the table. Some of these are structural, e.g., risk ratios for a cell with no follow-up time. |
| `conf.level` | confidence level for any confidence intervals |
| `scale` | a scaling factor for printed rates |
| `...` | optional arguments which will be passed to the `format` function; common choices would be digits=2 or nsmall=1. |

## Details

The `pyears` function is often used to create initial descriptions of a survival or time-to-event variable; the type of material that is often found in "table 1" of a paper. The summary routine prints this information out using one of pandoc table styles. A primary reason for choosing this style is that Rstudio is then able to automatically render the results in multiple formats: html, rtf, latex, etc.

If the `pyears` call has only a single covariate then the table will have that covariate as one margin and the statistics of interest as the other. If the `pyears` call has two predictors then those two predictors are used as margins of the table, while each cell of the table contains the statistics of interest as multiple rows within the cell. If there are more than two predictors then multiple tables are produced, in the same order as the standard R printout for an array.

The "N" entry of a pyears object is the number of observations which contributed to a particular cell. When the original call includes `tcut` objects then a single observation may contribute to multiple cells.

## Value

a copy of the object

## Notes

The pandoc system has four table types: with or without vertical bars, and with single or multiple rows of data in each cell. This routine produces all 4 styles depending on options, but currently not all of them are recognized by the Rstudio-pandoc pipeline. (And we don't yet see why.)

---

summary.survexp *Summary function for a survexp object*

---

### Description

Returns a list containing the values of the survival at specified times.

### Usage

```
## S3 method for class 'survexp'
summary(object, times, scale = 1, ...)
```

### Arguments

| | |
|---|---|
| object | the result of a call to the survexp function |
| times | vector of times; the returned matrix will contain 1 row for each time. Missing values are not allowed. |
| scale | numeric value to rescale the survival time, e.g., if the input data to survfit were in days, scale = 365.25 would scale the output to years. |
| ... | For future methods |

### Details

A primary use of this function is to retrieve survival at fixed time points, which will be properly interpolated by the function.

### Value

a list with the following components:

| | |
|---|---|
| surv | the estimate of survival at time t. |
| time | the timepoints on the curve. |
| n.risk | In expected survival each subject from the data set is matched to a hypothetical person from the parent population, matched on the characteristics of the parent population. The number at risk is the number of those hypothetical subject who are still part of the calculation. |

summary.survfit *Summary of a Survival Curve*

## Description

Returns a list containing the survival curve, confidence limits for the curve, and other information.

## Usage

```
  ## S3 method for class 'survfit'
summary(object, times=, censored=FALSE, scale=1,
  extend=FALSE, rmean=getOption('survfit.rmean'), ...)
```

## Arguments

| | |
|---|---|
| object | the result of a call to the survfit function. |
| times | vector of times; the returned matrix will contain 1 row for each time. The vector will be sorted into increasing order; missing values are not allowed. If censored=T, the default times vector contains all the unique times in fit, otherwise the default times vector uses only the event (death) times. |
| censored | logical value: should the censoring times be included in the output? This is ignored if the times argument is present. |
| scale | numeric value to rescale the survival time, e.g., if the input data to survfit were in days, scale = 365.25 would scale the output to years. |
| extend | logical value: if TRUE, prints information for all specified times, even if there are no subjects left at the end of the specified times. This is only valid if the times argument is present. |
| rmean | Show restricted mean: see print.survfit for details |
| ... | for future methods |

## Value

a list with the following components:

| | |
|---|---|
| surv | the estimate of survival at time t+0. |
| time | the timepoints on the curve. |
| n.risk | the number of subjects at risk at time t-0 (but see the comments on weights in the survfit help file). |
| n.event | if the times argument is missing, then this column is the number of events that occurred at time t. Otherwise, it is the cumulative number of events that have occurred since the last time listed until time t+0. |
| n.entered | This is present only for counting process survival data. If the times argument is missing, this column is the number of subjects that entered at time t. Otherwise, it is the cumulative number of subjects that have entered since the last time listed until time t. |

`n.exit.censored`
: if the `times` argument is missing, this column is the number of subjects that left without an event at time t. Otherwise, it is the cumulative number of subjects that have left without an event since the last time listed until time t+0. This is only present for counting process survival data.

`std.err`
: the standard error of the survival value.

`conf.int`
: level of confidence for the confidence intervals of survival.

`lower`
: lower confidence limits for the curve.

`upper`
: upper confidence limits for the curve.

`strata`
: indicates stratification of curve estimation. If `strata` is not `NULL`, there are multiple curves in the result and the `surv`, `time`, `n.risk`, etc. vectors will contain multiple curves, pasted end to end. The levels of `strata` (a factor) are the labels for the curves.

`call`
: the statement used to create the `fit` object.

`na.action`
: same as for `fit`, if present.

`table`
: table of information that is returned from `print.survfit` function.

`type`
: type of data censoring. Passed through from the fit object.

## See Also

`survfit`, `print.summary.survfit`

## Examples

summary( survfit( Surv(futime, fustat)~rx, data=ovarian))
```

---

`Surv` *Create a Survival Object*

---

## Description

Create a survival object, usually used as a response variable in a model formula. Argument matching is special for this function, see Details below.

## Usage

```
Surv(time, time2, event,
    type=c('right', 'left', 'interval', 'counting', 'interval2', 'mstate'),
    origin=0)
is.Surv(x)
```

## Arguments

`time`
: for right censored data, this is the follow up time. For interval data, the first argument is the starting time for the interval.

| | |
|---|---|
| `event` | The status indicator, normally 0=alive, 1=dead. Other choices are `TRUE/FALSE` (`TRUE` = death) or 1/2 (2=death). For interval censored data, the status indicator is 0=right censored, 1=event at `time`, 2=left censored, 3=interval censored. Although unusual, the event indicator can be omitted, in which case all subjects are assumed to have an event. |
| `time2` | ending time of the interval for interval censored or counting process data only. Intervals are assumed to be open on the left and closed on the right, `(start, end]`. For counting process data, `event` indicates whether an event occurred at the end of the interval. |
| `type` | character string specifying the type of censoring. Possible values are `"right"`, `"left"`, `"counting"`, `"interval"`, `"interval2"` or `"mstate"`. |
| `origin` | for counting process data, the hazard function origin. This option was intended to be used in conjunction with a model containing time dependent strata in order to align the subjects properly when they cross over from one strata to another, but it has rarely proven useful. |
| `x` | any R object. |

## Details

When the `type` argument is missing the code assumes a type based on the following rules:

- If there are two unnamed arguments, they will match `time` and `event` in that order. If there are three unnamed arguments they match `time`, `time2` and `event`.
- If the event variable is a factor then type `mstate` is assumed. Otherwise type `right` if there is no `time2` argument, and type `counting` if there is.

As a consequence the `type` argument will normally be omitted.

When the survival type is "mstate" then the status variable will be treated as a factor. The first level of the factor is taken to represent censoring and remaining ones a transition to the given state.

Interval censored data can be represented in two ways. For the first use `type = "interval"` and the codes shown above. In that usage the value of the `time2` argument is ignored unless event=3. The second approach is to think of each observation as a time interval with (-infinity, t) for left censored, (t, infinity) for right censored, (t,t) for exact and (t1, t2) for an interval. This is the approach used for type = interval2. Infinite values can be represented either by actual infinity (Inf) or NA. The second form has proven to be the more useful one.

Presently, the only methods allowing interval censored data are the parametric models computed by `survreg` and survival curves computed by `survfit`; for both of these, the distinction between open and closed intervals is unimportant. The distinction is important for counting process data and the Cox model.

The function tries to distinguish between the use of 0/1 and 1/2 coding for censored data via the condition `if (max(status)==2)`. If 1/2 coding is used and all the subjects are censored, it will guess wrong. In any questionable case it is safer to use logical coding, e.g., `Surv(time, status==3)` would indicate that a `3` is the code for an event.

For multi-state survival (type= "mstate") the status variable can have multiple levels. The first of these will stand for censoring, and the others for various event types, e.g., causes of death.

Surv objects can be subscripted either as a vector, e.g. `x[1:3]` using a single subscript, in which case the `drop` argument is ignored and the result will be a survival object; or as a matrix by using two subscripts. If the second subscript is missing and `drop=F` (the default), the result of the subscripting will be a Surv object, e.g., `x[1:3,,drop=F]`, otherwise the result will be a matrix (or vector), in accordance with the default behavior for subscripting matrices.

### Value

An object of class Surv. There are methods for print, is.na, and subscripting survival objects. Surv objects are implemented as a matrix of 2 or 3 columns that has further attributes. These include the type (left censored, right censored, counting process, etc.) and labels for the states for multi-state objects. Any attributes of the input arguments are also preserved in inputAttributes. This may be useful for other packages that have attached further information to data items such as labels; none of the routines in the survival package make use of these values, however.

In the case of is.Surv, a logical value TRUE if x inherits from class "Surv", otherwise an FALSE.

Surv(heart$start, heart$stop, heart$event)
```

---

## survConcordance *Compute a concordance measure.*

---

### Description

This function computes the concordance between a right-censored survival time and a single continuous covariate

### Usage

```
survConcordance(formula, data, weights, subset, na.action)
survConcordance.fit(y, x, strata, weight)
```

### Arguments

| | |
|---|---|
| formula | a formula with a survival time on the left and a single covariate on the right, along with an optional strata() term. The left hand term can also be a numeric vector. |
| data | a data frame |
| weights,subset,na.action | as for coxph |
| x, y, strata, weight | predictor, response, strata, and weight vectors for the direct call |

### Details

The survConcordance.fit function computes the result but does no data checking whatsoever. It is intended as a hook for other packages that wish to compute concordance, and the data has already been assembled and verified.

Concordance is defined as Pr(agreement) for any two randomly chosen observations, where in this case agreement means that the observation with the shorter survival time of the two also has the

larger risk score. The predictor (or risk score) will often be the result of a Cox model or other regression.

For continuous covariates concordance is equivalent to Kendall's tau, and for logistic regression is is equivalent to the area under the ROC curve. A value of 1 signifies perfect agreement, .6-.7 is a common result for survival data, .5 is an agreement that is no better than chance, and .3-.4 is the performance of some stock market analysts.

The computation involves all n(n-1)/2 pairs of data points in the sample. For survival data, however, some of the pairs are incomparable. For instance a pair of times (5+, 8), the first being a censored value. We do not know whether the first survival time is greater than or less than the second. Among observations that are comparable, pairs may also be tied on survival time (but only if both are uncensored) or on the predictor. The final concordance is (agree + tied/2)/(agree + disagree + tied).

There is, unfortunately, one aspect of the formula above that is unclear. Should the count of ties include observations that are tied on survival time y, tied on the predictor x, or both? By default the concordance only counts ties in x, treating tied survival times as incomparable; this agrees with the AUC calculation used in logistic regression. The Goodman-Kruskal Gamma statistic is (agree-disagree)/(agree + disagree), ignoring ties. It ranges from -1 to +1 similar to a correlation coefficient. Kendall's tau uses ties of both types. All of the components are returned in the result, however, so people can compute other combinations if interested. (If two observations have the same survival and the same x, they are counted in the tied survival time category).

The algorithm is based on a balanced binary tree, which allows the computation to be done in O(n log n) time.

## Value

an object containing the concordance, followed by the number of pairs that agree, disagree, are tied, and are not comparable.

## See Also

summary.coxph

## Examples

```
survConcordance(Surv(time, status) ~age, data=lung)

options(na.action=na.exclude)
fit <- coxph(Surv(time, status) ~ ph.ecog + age + sex, lung)
survConcordance(Surv(time, status) ~predict(fit), lung)
## Not run:
  n=227 (1 observations deleted due to missing values)
Concordance= 0.6371102 , Gamma= 0.2759638
concordant discordant  tied risk  tied time
     12544       7117        126         28

## End(Not run)
```

survdiff *Test Survival Curve Differences*

## Description

Tests if there is a difference between two or more survival curves using the $G^\rho$ family of tests, or for a single curve against a known alternative.

## Usage

```
survdiff(formula, data, subset, na.action, rho=0)
```

## Arguments

| | |
|---|---|
| formula | a formula expression as for other survival models, of the form `Surv(time, status) ~ predictors`. For a one-sample test, the predictors must consist of a single `offset(sp)` term, where `sp` is a vector giving the survival probability of each subject. For a k-sample test, each unique combination of predictors defines a subgroup. A `strata` term may be used to produce a stratified test. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the `strata` function with its `na.group=T` argument. |
| data | an optional data frame in which to interpret the variables occurring in the formula. |
| subset | expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating which observation numbers are to be included (or excluded if negative), or a character vector of row names to be included. All observations are included by default. |
| na.action | a missing-data filter function. This is applied to the `model.frame` after any subset argument has been used. Default is `options()$na.action`. |
| rho | a scalar parameter that controls the type of test. |

## Value

a list with components:

| | |
|---|---|
| n | the number of subjects in each group. |
| obs | the weighted observed number of events in each group. If there are strata, this will be a matrix with one column per stratum. |
| exp | the weighted expected number of events in each group. If there are strata, this will be a matrix with one column per stratum. |
| chisq | the chisquare statistic for a test of equality. |
| var | the variance matrix of the test. |
| strata | optionally, the number of subjects contained in each stratum. |

## METHOD

This function implements the G-rho family of Harrington and Fleming (1982), with weights on each death of $S(t)^\rho$, where $S(t)$ is the Kaplan-Meier estimate of survival. With `rho = 0` this is the log-rank or Mantel-Haenszel test, and with `rho = 1` it is equivalent to the Peto & Peto modification of the Gehan-Wilcoxon test.

If the right hand side of the formula consists only of an offset term, then a one sample test is done. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the `factor` function with its `exclude` argument.

## References

Harrington, D. P. and Fleming, T. R. (1982). A class of rank test procedures for censored survival data. *Biometrika* **69**, 553-566.

## Examples

```
## Two-sample test
survdiff(Surv(futime, fustat) ~ rx,data=ovarian)

## Stratified 7-sample test

survdiff(Surv(time, status) ~ pat.karno + strata(inst), data=lung)

## Expected survival for heart transplant patients based on
## US mortality tables
expect <- survexp(futime ~ ratetable(age=(accept.dt - birth.dt),
     sex=1,year=accept.dt,race="white"), jasa, cohort=FALSE,
     ratetable=survexp.usr)
## actual survival is much worse (no surprise)
survdiff(Surv(jasa$futime, jasa$fustat) ~ offset(expect))
```

---

`survexp` *Compute Expected Survival*

---

## Description

Returns either the expected survival of a cohort of subjects, or the individual expected survival for each subject.

## Usage

```
survexp(formula, data, weights, subset, na.action, rmap, times,
        method=c("ederer", "hakulinen", "conditional", "individual.h",
                 "individual.s"),
        cohort=TRUE, conditional=FALSE,
        ratetable=survival::survexp.us, scale=1,
        se.fit, model=FALSE, x=FALSE, y=FALSE)
```

## Arguments

| | |
|---|---|
| formula | formula object. The response variable is a vector of follow-up times and is optional. The predictors consist of optional grouping variables separated by the + operator (as in survfit), and is often ~1, i.e., expected survival for the entire group. |
| data | data frame in which to interpret the variables named in the formula, subset and weights arguments. |
| weights | case weights. This is most useful when conditional survival for a known population is desired, e.g., the data set would contain all unique age/sex combinations and the weights would be the proportion of each. |
| subset | expression indicating a subset of the rows of data to be used in the fit. |
| na.action | function to filter missing data. This is applied to the model frame after subset has been applied. Default is options()$na.action. |
| rmap | an optional list that maps data set names to the ratetable names. See the details section below. |
| times | vector of follow-up times at which the resulting survival curve is evaluated. If absent, the result will be reported for each unique value of the vector of times supplied in the response value of the formula. |
| method | computational method for the creating the survival curves. The individual option does not create a curve, rather it retrieves the predicted survival individual.s or cumulative hazard individual.h for each subject. The default is to use method='ederer' if the formula has no response, and method='hakulinen' otherwise. |
| cohort | logical value. This argument has been superseded by the method argument. To maintain backwards compatability, if is present and FALSE, it implies method='individual.s'. |
| conditional | logical value. This argument has been superseded by the method argument. To maintain backwards compatability, if it is present and TRUE it implies method='conditional'. |
| ratetable | a table of event rates, such as survexp.mn, or a fitted Cox model. Note the survival:: prefix in the default argument is present to avoid the (rare) case of a user who expects the default table but just happens to have an object named "survexp.us" in their own directory. |
| scale | numeric value to scale the results. If ratetable is in units/day, scale = 365.25 causes the output to be reported in years. |
| se.fit | compute the standard error of the predicted survival. This argument is currently ignored. Standard errors are not a defined concept for population rate tables (they are treated as coming from a complete census), and for Cox models the calculation is hard. Despite good intentions standard errors for this latter case have not been coded and validated. |
| model,x,y | flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments. |

## Details

Individual expected survival is usually used in models or testing, to 'correct' for the age and sex composition of a group of subjects. For instance, assume that birth date, entry date into the study,

sex and actual survival time are all known for a group of subjects. The survexp.us population tables contain expected death rates based on calendar year, sex and age. Then

```
haz <- survexp(fu.time ~ 1, data=mydata,
                    rmap = list(year=entry.dt, age=(birth.dt-entry.dt)),
                    method='individual.h'))
```

gives for each subject the total hazard experienced up to their observed death time or last follow-up time (variable fu.time) This probability can be used as a rescaled time value in models:

```
glm(status ~ 1 + offset(log(haz)), family=poisson)
glm(status ~ x + offset(log(haz)), family=poisson)
```

In the first model, a test for intercept=0 is the one sample log-rank test of whether the observed group of subjects has equivalent survival to the baseline population. The second model tests for an effect of variable x after adjustment for age and sex.

The ratetable being used may have different variable names than the user's data set, this is dealt with by the rmap argument. The rate table for the above calculation was survexp.us, a call to summary{survexp.us} reveals that it expects to have variables age = age in days, sex, and year = the date of study entry, we create them in the rmap line. The sex variable was not mapped, therefore the function assumes that it exists in mydata in the correct format. (Note: for factors such as sex, the program will match on any unique abbreviation, ignoring case.)

Cohort survival is used to produce an overall survival curve. This is then added to the Kaplan-Meier plot of the study group for visual comparison between these subjects and the population at large. There are three common methods of computing cohort survival. In the "exact method" of Ederer the cohort is not censored, for this case no response variable is required in the formula. Hakulinen recommends censoring the cohort at the anticipated censoring time of each patient, and Verheul recommends censoring the cohort at the actual observation time of each patient. The last of these is the conditional method. These are obtained by using the respective time values as the follow-up time or response in the formula.

## Value

if cohort=TRUE an object of class survexp, otherwise a vector of per-subject expected survival values. The former contains the number of subjects at risk and the expected survival for the cohort at each requested time. The cohort survival is the hypothetical survival for a cohort of subjects enrolled from the population at large, but matching the data set on the factors found in the rate table.

```

---

survexp.fit *Compute Expected Survival*

---

## Description

Compute expected survival times.

## Usage

```
survexp.fit(group, x, y, times, death, ratetable)
```

## Arguments

| | |
|---|---|
| group | if there are multiple survival curves this identifies the group, otherwise it is a constant. Must be an integer. |
| x | A matrix whose columns match the dimensions of the ratetable, in the correct order. |
| y | the follow up time for each subject. |
| times | the vector of times at which a result will be computed. |
| death | a logical value, if TRUE the conditional survival is computed, if FALSE the cohort survival is computed. See survexp for more details. |
| ratetable | a rate table, such as survexp.uswhite. |

## Details

For conditional survival y must be the time of last follow-up or death for each subject. For cohort survival it must be the potential censoring time for each subject, ignoring death.

For an exact estimate times should be a superset of y, so that each subject at risk is at risk for the entire sub-interval of time. For a large data set, however, this can use an inordinate amount of storage and/or compute time. If the times spacing is more coarse than this, an actuarial approximation is used which should, however, be extremely accurate as long as all of the returned values are > .99.

For a subgroup of size 1 and times > y, the conditional method reduces to exp(-h) where h is the expected cumulative hazard for the subject over his/her observation time. This is used to compute individual expected survival.

## Value

A list containing the number of subjects and the expected survival(s) at each time point. If there are multiple groups, these will be matrices with one column per group.

## Warning

Most users will call the higher level routine survexp. Consequently, this function has very few error checks on its input arguments.

## See Also

---

survexp.object *Expected Survival Curve Object*

---

## Description

This class of objects is returned by the survexp class of functions to represent a fitted survival curve.

Objects of this class have methods for summary, and inherit the print, plot, points and lines methods from survfit.

## Arguments

| | |
|---|---|
| surv | the estimate of survival at time t+0. This may be a vector or a matrix. |
| n.risk | the number of subjects who contribute at this time. |
| time | the time points at which the curve has a step. |
| std.err | the standard error of the cumulative hazard or -log(survival). |
| strata | if there are multiple curves, this component gives the number of elements of the time etc. vectors corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves. |
| method | the estimation method used. One of "Ederer", "Hakulinen", or "conditional". |
| na.action | the returned value from the na.action function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values. |
| call | an image of the call that produced the object. |

### Structure

The following components must be included in a legitimate `survfit` object.

### Subscripts

Survexp objects that contain multiple survival curves can be subscripted. This is most often used to plot a subset of the curves.

### Details

In expected survival each subject from the data set is matched to a hypothetical person from the parent population, matched on the characteristics of the parent population. The number at risk printed here is the number of those hypothetical subject who are still part of the calculation. In particular, for the Ederer method all hypotheticals are retained for all time, so `n.risk` will be a constant.

---

## `survfit` *Create survival curves*

---

### Description

This function creates survival curves from either a formula (e.g. the Kaplan-Meier), a previously fitted Cox model, or a previously fitted accelerated failure time model.

### Usage

```
survfit(formula, ...)
```

### Arguments

| | |
|---|---|
| `formula` | either a formula or a previously fitted model |
| `...` | other arguments to the specific method |

### Details

A survival curve is based on a tabulation of the number at risk and number of events at each unique death time. When time is a floating point number the definition of "unique" is subject to interpretation. The code uses factor() to define the set. For further details see the documentation for the appropriate method, i.e., `?survfit.formula` or `?survfit.coxph`.

A survfit object may contain a single curve, a set of curves, or a matrix curves. Predicted curves from a `coxph` model have one row for each stratum in the Cox model fit and one column for each specified covariate set. Curves from a multi-state model have one row for each stratum and a column for each state, the strata correspond to predictors on the right hand side of the equation. The default printing and plotting order for curves is by column, as with other matrices.

Curves can be subscripted using either a single or double subscript. If the set of curves is a matrix, as in the above, and one of the dimensions is 1 then the code allows a single subscript to be used. (That is, it is not quite as general as using a single subscript for a numeric matrix.)

## Value

An object of class `survfit` containing one or more survival curves.

## Note

Older releases of the code also allowed the specification for a single curve to omit the right hand of the formula, i.e., `survfit(Surv(time, status))`, in which case the formula argument is not actually a formula. Handling this case required some non-standard and fairly fragile manipulations, and this case is no longer supported.

---

`survfit.coxph` *Compute a Survival Curve from a Cox model*

---

## Description

Computes the predicted survivor function for a Cox proportional hazards model.

## Usage

```
## S3 method for class 'coxph'
survfit(formula, newdata,
        se.fit=TRUE, conf.int=.95,
        individual=FALSE,
        type,vartype,
        conf.type=c("log","log-log","plain","none"), censor=TRUE, id,
        start.time,
        na.action=na.pass, ...)
```

## Arguments

| | |
|---|---|
| `formula` | A `coxph` object. |
| `newdata` | a data frame with the same variable names as those that appear in the `coxph` formula. It is also valid to use a vector, if the data frame would consist of a single row.<br>The curve(s) produced will be representative of a cohort whose covariates correspond to the values in `newdata`. Default is the mean of the covariates used in the `coxph` fit. |
| `individual` | This argument has been superseded by the `id` argument and is present only for backwards compatability. A logical value indicating whether each row of `newdata` represents a distinct individual (FALSE, the default), or if each row of the data frame represents different time epochs for only one individual (TRUE). In the former case the result will have one curve for each row in `newdata`, in the latter only a single curve will be produced. |

`conf.int` the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.

`se.fit` a logical value indicating whether standard errors should be computed. Default is `TRUE`.

`type,vartype` a character string specifying the type of survival curve. Possible values are `"aalen"`, `"efron"`, or `"kalbfleisch-prentice"` (only the first two characters are necessary). The default is to match the computation used in the Cox model. The Nelson-Aalen-Breslow estimate for `ties='breslow'`, the Efron estimate for `ties='efron'` and the Kalbfleisch-Prentice estimate for a discrete time model `ties='exact'`. Variance estimates are the Aalen-Link-Tsiatis, Efron, and Greenwood. The default will be the Efron estimate for `ties='efron'` and the Aalen estimate otherwise.

`conf.type` One of `"none"`, `"plain"`, `"log"` (the default), or `"log-log"`. Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals `curve +- k *se(curve)`, where k is determined from `conf.int`. The log option calculates intervals based on the cumulative hazard or log(survival). The last option bases intervals on the log hazard or log(-log(survival)).

`censor` if FALSE time points at which there are no events (only censoring) are not included in the result.

`id` optional variable name of subject identifiers. If this is present, then each group of rows with the same subject id represents the covariate path through time of a single subject, and the result will contain one curve per subject. If the `coxph` fit had strata then that must also be specified in `newdata`. If missing, then each individual row of `newdata` is presumed to represent a distinct subject and there will be `nrow(newdata)` times the number of strata curves in the result (one for each strata/subject combination). result.

`start.time` optional starting time, a single numeric value. If present the returned curve contains survival after `start.time` conditional on surviving to `start.time`.

`na.action` the na.action to be used on the newdata argument

`...` for future methods

## Details

Serious thought has been given to removing the default value for `newdata`, which is to use a single "pseudo" subject with covariate values equal to the means of the data set, since the resulting curve(s) almost never make sense. It remains due to an unwarranted attachment to the option shown by some users and by other packages. Two particularly egregious examples are factor variables and interactions. Suppose one were studying interspecies transmission of a virus, and the data set has a factor variable with levels ("pig", "chicken") and about equal numbers of observations for each. The “mean” covariate level will be 1/2 – is this a flying pig? As to interactions assume data with sex coded as 0/1, ages ranging from 50 to 80, and a model with age*sex. The “mean” value for the age:sex interaction term will be about 30, a value that does not occur in the data. Users are strongly advised to use the newdata argument.

When the original model contains time-dependent covariates, then the path of that covariate through time needs to be specified in order to obtain a predicted curve. This requires `newdata` to contain multiple lines for each hypothetical subject which gives the covariate values, time interval, and strata for each line (a subject can change strata), along with an `id` variable which demarks which rows belong to each subject. The time interval must have the same (start, stop, status) variables as the original model: although the status variable is not used and thus can be set to a dummy value of

0 or 1, it is necessary for the variables to be recognized as a `Surv` object. Last, although predictions with a time-dependent covariate path can be useful, it is very easy to create a prediction that is senseless. Users are encouraged to seek out a text that discusses the issue in detail.

When a model contains strata but no time-dependent covariates the user of this routine has a choice. If newdata argument does not contain strata variables then the returned object will be a matrix of survival curves with one row for each strata in the model and one column for each row in newdata. (This is the historical behavior of the routine.) If newdata does contain strata variables, then the result will contain one curve per row of newdata, based on the indicated stratum of the original model. In the rare case of a model with strata by covariate interactions the strata variable must be included in newdata, the routine does not allow it to be omitted (predictions become too confusing). (Note that the model Surv(time, status) ~ age*strata(sex) expands internally to strata(sex) + age:sex; the sex variable is needed for the second term of the model.)

When all the coefficients are zero, the Kalbfleisch-Prentice estimator reduces to the Kaplan-Meier, the Aalen estimate to the exponential of Nelson's cumulative hazard estimate, and the Efron estimate to the Fleming-Harrington estimate of survival. The variances of the curves from a Cox model are larger than these non-parametric estimates, however, due to the variance of the coefficients.

See `survfit` for more details about the counts (number of events, number at risk, etc.)

The censor argument was fixed at FALSE in earlier versions of the code and not made available to the user. The default argument is sensible in most instances — and causes the familiar + sign to appear on plots — it is not sensible for time dependent covariates since it may lead to a large number of spurious marks.

## Value

an object of class `"survfit"`. See `survfit.object` for details. Methods defined for survfit objects are `print`, `plot`, `lines`, and `points`.

## Notes

If the following pair of lines is used inside of another function then the `model=TRUE` argument must be added to the coxph call: `fit <- coxph(...); survfit(fit)`. This is a consequence of the non-standard evaluation process used by the `model.frame` function when a formula is involved.

---

`survfit.formula` *Compute a Survival Curve for Censored Data*

---

## Description

Computes an estimate of a survival curve for censored data. More multi-state data the Andersen-Johansen estimate is use, for ordinary survival either the Kaplan-Meier or Fleming-Harrington estimate is produced.

## Usage

```
## S3 method for class 'formula'
survfit(formula, data, weights, subset, na.action,
        etype, id, istate, timefix=TRUE, ...)
```

## Arguments

`formula` a formula object, which must have a `Surv` object as the response on the left of the ~ operator and, if desired, terms separated by + operators on the right. One of the terms may be a `strata` object. For a single survival curve the right hand side should be `~ 1`.

`data` a data frame in which to interpret the variables named in the formula, `subset` and `weights` arguments.

`weights` The weights must be nonnegative and it is strongly recommended that they be strictly positive, since zero weights are ambiguous, compared to use of the `subset` argument.

`subset` expression saying that only a subset of the rows of the data should be used in the fit.

`na.action` a missing-data filter function, applied to the model frame, after any `subset` argument has been used. Default is `options()$na.action`.

`etype` a variable giving the type of event. This has been superseded by multi-state Surv objects; see example below.

`id` identifies individual subjects, when a given person can have multiple lines of data.

`istate` for multi-state models, identifies the initial state of each subject

`timefix` process times through the `aeqSurv` function to eliminate potential roundoff issues.

`...` The following additional arguments are passed to internal functions called by `survfit`.

**type** a character string specifying the type of survival curve. Possible values are `"kaplan-meier"`, `"fleming-harrington"` or `"fh2"` if a formula is given. This is ignored for competing risks or when the Turnbull estimator is used.

**error** a character string specifying the error. Possible values are `"greenwood"` for the Greenwood formula or `"tsiatis"` or `"aalen"` for the Tsiatis/Aalen formula, or `"robust"` for a robust variance. The last of these is assumed if non-integer case weights are provided.

**conf.type** One of `"none"`, `"plain"`, `"log"` (the default), or `"log-log"`. Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals `curve +- k *se(curve)`, where k is determined from `conf.int`. The log option calculates intervals based on the cumulative hazard or log(survival). The last option bases intervals on the log hazard or log(-log(survival)).

**conf.lower** a character string to specify modified lower limits to the curve, the upper limit remains unchanged. Possible values are `"usual"` (unmodified), `"peto"`, and `"modified"`. T he modified lower limit is based on an "effective n" argument. The confidence bands will agree with the usual calculation at each death time, but unlike the usual bands the confidence interval becomes wider at each censored observation. The extra width is obtained

by multiplying the usual variance by a factor m/n, where n is the number currently at risk and m is the number at risk at the last death time. (The bands thus agree with the un-modified bands at each death time.) This is especially useful for survival curves with a long flat tail.
The Peto lower limit is based on the same "effective n" argument as the modified limit, but also replaces the usual Greenwood variance term with a simple approximation. It is known to be conservative.

**start.time** numeric value specifying a time to start calculating survival information. The resulting curve is the survival conditional on surviving to `start.time`.

**conf.int** the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.

**se.fit** a logical value indicating whether standard errors should be computed. Default is `TRUE`.

**influence** a logical value indicating whether to return the infinitesimal jackknife (influence) values for each subject. These contain the values of the derivative of each value with respect to the case weights of each subject i: $\partial p/\partial w_i$, evaluated at the vector of weights $w = 1$. The array will have dimensions (number of subjects, 1+ number of unique times, number of states); be forewarned that this can be huge. If the total number of elements is larger then the maximum integer the underlying C program can not create it.

## Details

The estimates used are the Kalbfleisch-Prentice (Kalbfleisch and Prentice, 1980, p.86) and the Tsiatis/Link/Breslow, which reduce to the Kaplan-Meier and Fleming-Harrington estimates, respectively, when the weights are unity.

The Greenwood formula for the variance is a sum of terms d/(n*(n-m)), where d is the number of deaths at a given time point, n is the sum of weights for all individuals still at risk at that time, and m is the sum of weights for the deaths at that time. The justification is based on a binomial argument when weights are all equal to one; extension to the weighted case is ad hoc. Tsiatis (1981) proposes a sum of terms d/(n*n), based on a counting process argument which includes the weighted case.

The two variants of the F-H estimate have to do with how ties are handled. If there were 3 deaths out of 10 at risk, then the first increments the hazard by 3/10 and the second by 1/10 + 1/9 + 1/8. For the first method S(t) = exp(H), where H is the Nelson-Aalen cumulative hazard estimate, whereas the `fh2` method will give results S(t) results closer to the Kaplan-Meier.

When the data set includes left censored or interval censored data (or both), then the EM approach of Turnbull is used to compute the overall curve. When the baseline method is the Kaplan-Meier, this is known to converge to the maximum likelihood estimate.

The cumulative incidence curve is an alternative to the Kaplan-Meier for competing risks data. For instance, in patients with MGUS, conversion to an overt plasma cell malignancy occurs at a nearly constant rate among those still alive. A Kaplan-Meier estimate, treating death due to other causes as censored, gives a 20 year cumulate rate of 33% for the 241 early patients of Kyle. This estimates the incidence of conversion if all other causes of death were removed, which is an unrealistic assumption given the mean starting age of 63 and a median follow up of over 21 years.

The CI estimate, on the other hand, estimates the total number of conversions that will actually occur. Because the population is older, this is much smaller than the KM, 22% at 20 years for Kyle's data. If there were no censoring, then CI(t) could very simply be computed as total number of patients with progression by time t divided by the sample size n.

## Value

an object of class "survfit". See survfit.object for details. Methods defined for survfit objects are print, plot, lines, and points.

---

`survfit.matrix` *Create Aalen-Johansen estimates of multi-state survival from a matrix of hazards.*

---

## Description

This allows one to create the Aalen-Johansen estimate of P, a matrix with one column per state and one row per time, starting with the individual hazard estimates. Each row of P will sum to 1.

## Usage

```
## S3 method for class 'matrix'
survfit(formula, p0, method = c("discrete", "matexp"), ...)
```

## Arguments

| | |
|---|---|
| `formula` | a matrix of lists, each element of which is either NULL or a survival curve object. |
| `p0` | the initial state vector. The names of this vector are used as the names of the states in the output object. If there are multiple curves then `p0` can be a matrix with one row per curve. |
| `method` | use a product of discrete hazards, or a product of matrix exponentials. See details below. |
| `...` | further arguments for other methods |

## Details

On input the matrix should contain a set of predicted curves for each possible transition, and NULL in other positions. Each of the predictions will have been obtained from the relevant Cox model. This approach for multistate curves is easy to use but has some caveats. First, the input curves must be consistent. The routine checks as best it can, but can easy be fooled. For instance, if one were to fit two Cox models, obtain predictions for males and females from one, and for treatment A and

B from the other, this routine will create two curves but they are not meaningful. A second issue is that standard errors are not produced.

The names of the resulting states are taken from the names of the vector of initial state probabilities. If they are missing, then the dimnames of the input matrix are used, and lacking that the labels '1', '2', etc. are used.

For the usual Aalen-Johansen estimator the multiplier at each event time is the matrix of hazards H (also written as I + dA). When using predicted survival curves from a Cox model, however, it is possible to get predicted hazards that are greater than 1, which leads to probabilities less than 0. If the `method` argument is not supplied and the input curves are derived from a Cox model this routine instead uses the approximation expm(H-I) as the multiplier, which always gives valid probabilities. (This is also the standard approach for ordinary survival curves from a Cox model.)

## Value

a survfitms object

## Note

The R syntax for creating a matrix of lists is very fussy.

## Author(s)

Terry Therneau

## Examples

```
etime <- with(mgus2, ifelse(pstat==0, futime, ptime))
event <- with(mgus2, ifelse(pstat==0, 2*death, 1))
event <- factor(event, 0:2, labels=c("censor", "pcm", "death"))

cfit1 <- coxph(Surv(etime, event=="pcm") ~ age + sex, mgus2)
cfit2 <- coxph(Surv(etime, event=="death") ~ age + sex, mgus2)

# predicted competing risk curves for a 72 year old with mspike of 1.2
# (median values), male and female.
# The survfit call is a bit faster without standard errors.
newdata <- expand.grid(sex=c("F", "M"), age=72, mspike=1.2)

AJmat <- matrix(list(), 3,3)
AJmat[1,2] <- list(survfit(cfit1, newdata, std.err=FALSE))
AJmat[1,3] <- list(survfit(cfit2, newdata, std.err=FALSE))
csurv  <- survfit(AJmat, p0 =c(entry=1, PCM=0, death=0))
```

survfit.object *Survival Curve Object*

## Description

This class of objects is returned by the survfit class of functions to represent a fitted survival curve. For a multi-state model the object has class c('survfitms', 'survfit').

Objects of this class have methods for the functions print, summary, plot, points and lines. The print.survfit method does more computation than is typical for a print method and is documented on a separate page.

## Arguments

| | |
|---|---|
| n | total number of subjects in each curve. |
| time | the time points at which the curve has a step. |
| n.risk | the number of subjects at risk at t. |
| n.event | the number of events that occur at time t. |
| n.enter | for counting process data only, the number of subjects that enter at time t. |
| n.censor | for counting process data only, the number of subjects who exit the risk set, without an event, at time t. (For right censored data, this number can be computed from the successive values of the number at risk). |
| surv | the estimate of survival at time t+0. This may be a vector or a matrix. The latter occurs when a set of survival curves is created from a single Cox model, in which case there is one column for each covariate set. |
| prev, p0 | a multi-state survival will have the prev component instead of surv. It will be a matrix containing the estimated probability of each state at each time, one column per state. The p0 matrix contains the initial distribution of states. (On further reflection pstate= "probability in state" would have been a much better label than "prevalence", but by that point too many other packages were dependent on the form of the result.) |
| std.err | for a survival curve this contains standard error of the cumulative hazard or -log(survival), for a multi-state curve it contains the standard error of prev. This difference is a reflection of the fact that each is the natural calculation for that case. |
| cumhaz hazard | optional. For a multi-state curve this is an k by k array for each time point, where k is the number of states. |
| upper | upper confidence limit for the survival curve or probability |
| lower | lower confidence limit for the survival curve or probability |
| strata | if there are multiple curves, this component gives the number of elements of the time etc. vectors corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves. |
| start.time | the value specified for the start.time argument, if it was used in the call. |
| n.all | for counting process data, and any time that the start.time argument was used, this contains the total number of observations that were available. Not all may have been used in creating the curve, in which case this value will be larger than n above. |

| | |
|---|---|
| conf.type | the approximation used to compute the confidence limits. |
| conf.int | the level of the confidence limits, e.g. 90 or 95%. |
| transitions | for multi-state data, the total number of transitions of each type. |
| na.action | the returned value from the na.action function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values. |
| call | an image of the call that produced the object. |
| type | type of survival censoring. |
| influence | optional, for survfitms objects only. A list with one element per stratum, each element of the list is an array indexed by subject, time, state. The time dimension will have one more element than the prev matrix, the first row is the subject's influence on the initial prevalence (just before the first time point). If there is only one curve a list is not needed. |

## Structure

The following components must be included in a legitimate survfit or survfitms object.

## Subscripts

Survfit objects that contain multiple survival curves can be subscripted. This is often used to plot a subset of the curves. If the surv or prev component is a matrix then the survfit object will be treated as a matrix, otherwise only a single subscript is used.

## See Also

plot.survfit, summary.survfit, print.survfit, survfit.

---

survfitcoxph.fit *A direct interface to the 'computational engine' of survfit.coxph*

---

## Description

This program is mainly supplied to allow other packages to invoke the survfit.coxph function at a 'data' level rather than a 'user' level. It does no checks on the input data that is provided, which can lead to unexpected errors if that data is wrong.

## Usage

```
survfitcoxph.fit(y, x, wt, x2, risk, newrisk, strata, se.fit, survtype,
vartype, varmat, id, y2, strata2, unlist=TRUE)
```

## Arguments

| | |
|---|---|
| y | the response variable used in the Cox model. (Missing values removed of course.) |
| x | covariate matrix used in the Cox model |
| wt | weight vector for the Cox model. If the model was unweighted use a vector of 1s. |

| | |
|---|---|
| x2 | matrix describing the hypothetical subjects for which a curve is desired. Must have the same number of columns as x. |
| risk | the risk score exp(X beta) from the fitted Cox model. If the model had an offset, include it in the argument to exp. |
| newrisk | risk scores for the hypothetical subjects |
| strata | strata variable used in the Cox model. This will be a factor. |
| se.fit | if TRUE the standard errors of the curve(s) are returned |
| survtype | 1=Kalbfleisch-Prentice, 2=Nelson-Aalen, 3=Efron. It is usual to match this to the approximation for ties used in the coxph model: KP for 'exact', N-A for 'breslow' and Efron for 'efron'. |
| vartype | 1=Greenwood, 2=Aalen, 3=Efron |
| varmat | the variance matrix of the coefficients |
| id | optional; if present and not NULL this should be a vector of identifiers of length nrow(x2). A mon-null value signifies that x2 contains time dependent covariates, in which case this identifies which rows of x2 go with each subject. |
| y2 | survival times, for time dependent prediction. It gives the time range (time1,time2] for each row of x2. Note: this must be a Surv object and thus contains a status indicator, which is never used in the routine, however. |
| strata2 | vector of strata indicators for x2. This must be a factor. |
| unlist | if FALSE the result will be a list with one element for each strata. Otherwise the strata are "unpacked" into the form found in a survfit object. |

## Value

a list containing nearly all the components of a survfit object. All that is missing is to add the confidence intervals, the type of the original model's response (as in a coxph object), and the class.

## Note

The source code for for both this function and survfit.coxph is written using noweb. For complete documentation see the inst/sourcecode.pdf file.

survobrien *O'Brien's Test for Association of a Single Variable with Survival*

## Description

Peter O'Brien's test for association of a single variable with survival This test is proposed in Biometrics, June 1978.

## Usage

```
survobrien(formula, data, subset, na.action, transform)
```

## Arguments

| | |
|---|---|
| formula | a valid formula for a cox model. |
| data | a data.frame in which to interpret the variables named in the formula, or in the subset and the weights argument. |
| subset | expression indicating which subset of the rows of data should be used in the fit. All observations are included by default. |
| na.action | a missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is options()$na.action. |
| transform | the transformation function to be applied at each time point. The default is O'Brien's suggestion logit(tr) where tr = (rank(x)- 1/2)/ length(x) is the rank shifted to the range 0-1 and logit(x) = log(x/(1-x)) is the logit transform. |

## Value

a new data frame. The response variables will be column names returned by the Surv function, i.e., "time" and "status" for simple survival data, or "start", "stop", "status" for counting process data. Each individual event time is identified by the value of the variable .strata.. Other variables retain their original names. If a predictor variable is a factor or is protected with I(), it is retained as is. Other predictor variables have been replaced with time-dependent logit scores.

The new data frame will have many more rows that the original data, approximately the original number of rows * number of deaths/2.

## Method

A time-dependent cox model can now be fit to the new data. The univariate statistic, as originally proposed, is equivalent to single variable score tests from the time-dependent model. This equivalence is the rationale for using the time dependent model as a multivariate extension of the original paper.

In O'Brien's method, the x variables are re-ranked at each death time. A simpler method, proposed by Prentice, ranks the data only once at the start. The results are usually similar.

## Note

A prior version of the routine returned new time variables rather than a strata. Unfortunately, that strategy does not work if the original formula has a strata statement. This new data set will be the same size, but the coxph routine will process it slightly faster.

## Examples

```
xx <- survobrien(Surv(futime, fustat) ~ age + factor(rx) + I(ecog.ps),
       data=ovarian)
coxph(Surv(time, status) ~ age + strata(.strata.), data=xx)
```

---

survreg *Regression for a Parametric Survival Model*

---

## Description

Fit a parametric survival regression model. These are location-scale models for an arbitrary transform of the time variable; the most common cases use a log transformation, leading to accelerated failure time models.

## Usage

```
survreg(formula, data, weights, subset,
        na.action, dist="weibull", init=NULL, scale=0,
        control,parms=NULL,model=FALSE, x=FALSE,
        y=TRUE, robust=FALSE, score=FALSE, ...)
```

## Arguments

| | |
|---|---|
| formula | a formula expression as for other regression models. The response is usually a survival object as returned by the Surv function. See the documentation for Surv, lm and formula for details. |
| data | a data frame in which to interpret the variables named in the formula, weights or the subset arguments. |
| weights | optional vector of case weights |
| subset | subset of the observations to be used in the fit |
| na.action | a missing-data filter function, applied to the model.frame, after any subset argument has been used. Default is options()$na.action. |
| dist | assumed distribution for y variable. If the argument is a character string, then it is assumed to name an element from survreg.distributions. These include "weibull", "exponential", "gaussian", "logistic","lognormal" and "loglogistic". Otherwise, it is assumed to be a user defined list conforming to the format described in survreg.distributions. |
| parms | a list of fixed parameters. For the t-distribution for instance this is the degrees of freedom; most of the distributions have no parameters. |

| | |
|---|---|
| `init` | optional vector of initial values for the parameters. |
| `scale` | optional fixed value for the scale. If set to <=0 then the scale is estimated. |
| `control` | a list of control values, in the format produced by `survreg.control`. The default value is `survreg.control()` |
| `model,x,y` | flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments. |
| `score` | return the score vector. (This is expected to be zero upon successful convergence.) |
| `robust` | Use robust 'sandwich' standard errors, based on independence of individuals if there is no `cluster()` term in the formula, based on independence of clusters if there is. |
| `...` | other arguments which will be passed to `survreg.control`. |

## Details

All the distributions are cast into a location-scale framework, based on chapter 2.2 of Kalbfleisch and Prentice. The resulting parameterization of the distributions is sometimes (e.g. gaussian) identical to the usual form found in statistics textbooks, but other times (e.g. Weibull) it is not. See the book for detailed formulas.

## Value

an object of class `survreg` is returned.

## Examples

```
# Fit an exponential model: the two fits are the same
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian, dist='weibull',
                                  scale=1)
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian,
        dist="exponential")

#
# A model with different baseline survival shapes for two groups, i.e.,
#   two different scale parameters
survreg(Surv(time, status) ~ ph.ecog + age + strata(sex), lung)

# There are multiple ways to parameterize a Weibull distribution. The survreg
# function embeds it in a general location-scale family, which is a
# different parameterization than the rweibull function, and often leads
# to confusion.
#   survreg's scale  =    1/(rweibull shape)
#   survreg's intercept = log(rweibull scale)
#   For the log-likelihood all parameterizations lead to the same value.
```

```
y <- rweibull(1000, shape=2, scale=5)
survreg(Surv(y)~1, dist="weibull")

# Economists fit a model called `tobit regression', which is a standard
# linear regression with Gaussian errors, and left censored data.
tobinfit <- survreg(Surv(durable, durable>0, type='left') ~ age + quant,
            data=tobin, dist='gaussian')
```

---

survreg.control *Package options for survreg and coxph*

---

## Description

This functions checks and packages the fitting options for survreg

## Usage

```
survreg.control(maxiter=30, rel.tolerance=1e-09,
toler.chol=1e-10, iter.max, debug=0, outer.max=10)
```

## Arguments

| | |
|---|---|
| maxiter | maximum number of iterations |
| rel.tolerance | relative tolerance to declare convergence |
| toler.chol | Tolerance to declare Cholesky decomposition singular |
| iter.max | same as maxiter |
| debug | print debugging information |
| outer.max | maximum number of outer iterations for choosing penalty parameters |

## Value

A list with the same elements as the input

## See Also

survreg

survreg.distributions *Parametric Survival Distributions*

## Description

List of distributions for accelerated failure models. These are location-scale families for some transformation of time. The entry describes the cdf $F$ and density $f$ of a canonical member of the family.

## Usage

```
survreg.distributions
```

## Format

There are two basic formats, the first defines a distribution de novo, the second defines a new distribution in terms of an old one.

| | |
|---|---|
| name: | name of distribution |
| variance: | function(parms) returning the variance (currently unused) |
| init(x,weights,...): | Function returning an initial estimate of the mean and variance (used for initial values in the iteration) |
| density(x,parms): | Function returning a matrix with columns $F$, $1-F$,$f$,$f'/f$,$f''/f$ |
| quantile(p,parms): | Quantile function |
| scale: | Optional fixed value for the scale parameter |
| parms: | Vector of default values and names for any additional parameters |
| deviance(y,scale,parms): | Function returning the deviance for a saturated model; used only for deviance residuals. |

and to define one distribution in terms of another

| | |
|---|---|
| name: | name of distribution |
| dist: | name of parent distribution |
| trans: | transformation (eg log) |
| dtrans: | derivative of transformation |
| itrans: | inverse of transformation |
| scale: | Optional fixed value for scale parameter |

## Details

There are four basic distributions:`extreme`, `gaussian`, `logistic` and `t`. The last three are parametrised in the same way as the distributions already present in R. The extreme value cdf is

$$F = 1 - e^{-e^t}.$$

When the logarithm of survival time has one of the first three distributions we obtain respectively `weibull`, `lognormal`, and `loglogistic`. The location-scale parameterization of a Weibull distribution found in `survreg` is not the same as the parameterization of `rweibull`.

The other predefined distributions are defined in terms of these. The `exponential` and `rayleigh` distributions are Weibull distributions with fixed `scale` of 1 and 0.5 respectively, and `loggaussian` is a synonym for `lognormal`.

For speed parts of the three most commonly used distributions are hardcoded in C; for this reason the elements of `survreg.distributions` with names of "Extreme value", "Logistic" and "Gaussian" should not be modified. (The order of these in the list is not important, recognition is by name.) As an alternative to modifying `survreg.distributions` a new distribution can be specified as a separate list. This is the preferred method of addition and is illustrated below.

## Examples

```
# time transformation
survreg(Surv(time, status) ~ ph.ecog + sex, dist='weibull', data=lung)
# change the transformation to work in years
# intercept changes by log(365), everything else stays the same
my.weibull <- survreg.distributions$weibull
my.weibull$trans <- function(y) log(y/365)
my.weibull$itrans <- function(y) 365*exp(y)
survreg(Surv(time, status) ~ ph.ecog + sex, lung, dist=my.weibull)

# Weibull parametrisation
y<-rweibull(1000, shape=2, scale=5)
survreg(Surv(y)~1, dist="weibull")
# survreg scale parameter maps to 1/shape, linear predictor to log(scale)

# Cauchy fit
mycauchy <- list(name='Cauchy',
                 init= function(x, weights, ...)
                      c(median(x), mad(x)),
                 density= function(x, parms) {
                      temp <- 1/(1 + x^2)
                      cbind(.5 + atan(x)/pi, .5+ atan(-x)/pi,
                            temp/pi, -2 *x*temp, 2*temp*(4*x^2*temp -1))
                      },
                 quantile= function(p, parms) tan((p-.5)*pi),
                 deviance= function(...) stop('deviance residuals not defined')
                 )
survreg(Surv(log(time), status) ~ ph.ecog + sex, lung, dist=mycauchy)
```

---

`survreg.object` *Parametric Survival Model Object*

---

## Description

This class of objects is returned by the `survreg` function to represent a fitted parametric survival model. Objects of this class have methods for the functions `print`, `summary`, `predict`, and `residuals`.

## COMPONENTS

The following components must be included in a legitimate `survreg` object.

**coefficients** the coefficients of the `linear.predictors`, which multiply the columns of the model matrix. It does not include the estimate of error (sigma). The names of the coefficients are the names of the single-degree-of-freedom effects (the columns of the model matrix). If the model is over-determined there will be missing values in the coefficients corresponding to non-estimable coefficients.

**icoef** coefficients of the baseline model, which will contain the intercept and log(scale), or multiple scale factors for a stratified model.

**var** the variance-covariance matrix for the parameters, including the log(scale) parameter(s).

**loglik** a vector of length 2, containing the log-likelihood for the baseline and full models.

**iter** the number of iterations required

**linear.predictors** the linear predictor for each subject.

**df** the degrees of freedom for the final model. For a penalized model this will be a vector with one element per term.

**scale** the scale factor(s), with length equal to the number of strata.

**idf** degrees of freedom for the initial model.

**means** a vector of the column means of the coefficient matrix.

**dist** the distribution used in the fit.

**weights** included for a weighted fit.

The object will also have the following components found in other model results (some are optional): `linear predictors`, `weights`, `x`, `y`, `model`, `call`, `terms` and `formula`. See `lm`.

---

`survregDtest` *Verify a survreg distribution*

---

## Description

This routine is called by `survreg` to verify that a distribution object is valid.

## Usage

```
survregDtest(dlist, verbose = F)
```

## Arguments

| | |
|---|---|
| `dlist` | the list describing a survival distribution |
| `verbose` | return a simple TRUE/FALSE from the test for validity (the default), or a verbose description of any flaws. |

## Details

If the survreg function rejects your user-supplied distribution as invalid, this routine will tell you why it did so.

## Value

TRUE if the distribution object passes the tests, and either FALSE or a vector of character strings if not.

## Author(s)

Terry Therneau

## See Also

survreg.distributions, survreg

## Examples

```
# An invalid distribution (it should have "init =" on line 2)
#  surveg would give an error message
mycauchy <- list(name='Cauchy',
                 init<- function(x, weights, ...)
                      c(median(x), mad(x)),
                 density= function(x, parms) {
                      temp <- 1/(1 + x^2)
                      cbind(.5 + atan(temp)/pi, .5+ atan(-temp)/pi,
                            temp/pi, -2 *x*temp, 2*temp^2*(4*x^2*temp -1))
                      },
                 quantile= function(p, parms) tan((p-.5)*pi),
                 deviance= function(...) stop('deviance residuals not defined')
                 )

survregDtest(mycauchy, TRUE)
```

---

survSplit *Split a survival data set at specified times*

---

## Description

Given a survival data set and a set of specified cut times, split each record into multiple subrecords at each cut time. The new data set will be in 'counting process' format, with a start time, stop time, and event status for each record.

## Usage

```
survSplit(formula, data, subset, na.action=na.pass,
            cut, start="tstart", id, zero=0, episode,
                                 end="tstop", event="event")
```

## Arguments

| | |
|---|---|
| formula | a model formula |
| data | a data frame |
| subset, na.action | rows of the data to be retained |
| cut | the vector of timepoints to cut at |
| start | character string with the name of a start time variable (will be created if needed) |
| id | character string with the name of new id variable to create (optional). This can be useful if the data set does not already contain an identifier. |
| zero | If `start` doesn't already exist, this is the time that the original records start. |
| episode | character string with the name of new episode variable (optional) |
| end | character string with the name of event time variable |
| event | character string with the name of censoring indicator |

## Details

Each interval in the original data is cut at the given points; if an original row were (15, 60] with a cut vector of (10,30, 40) the resulting data set would have intervals of (15,30], (30,40] and (40, 60].

Each row in the final data set will lie completely within one of the cut intervals. Which interval for each row of the output is shown by the `episode` variable, where 1= less than the first cutpoint, 2= between the first and the second, etc. For the example above the values would be 2, 3, and 4.

The routine will normally be called with a formula as the first argument. The right hand side of the formula can be used to delimit variables that should be retained; normally one will use `~ .` as a shorthand to retain them all. When called in this way the routine will try to retain variable names, e.g. `Surv(adam, joe, fred)~.` will result in a data set with those same variable names for `tstart`, `end`, and `event` options rather than the defaults. Any user specified values for these options will be used if they are present, of course. However, the routine is not sophisticated; it only does this substitution for simple names. A call of `Surv(time, stat==2)` for instance will result in use of the 'event' argument for that variable name. The `end` and `event` arguments are required if there is no formula.

Rows of data with a missing time or status are copied across unchanged, unless the na.action argument is changed from its default value of `na.pass`. But in the latter case any row that is missing for any variable will be removed, which is rarely what is desired.

## Value

New, longer, data frame.

## See Also

`Surv`, `cut`, `reshape`

## Examples

```
fit1 <- coxph(Surv(time, status) ~ karno + age + trt, veteran)
plot(cox.zph(fit1)[1])
# a cox.zph plot of the data suggests that the effect of Karnofsky score
#  begins to diminish by 60 days and has faded away by 120 days.
# Fit a model with separate coefficients for the three intervals.
#
```

```
vet2 <- survSplit(Surv(time, status) ~., veteran,
                  cut=c(60, 120), episode ="timegroup")
fit2 <- coxph(Surv(tstart, time, status) ~ karno* strata(timegroup) +
                age + trt, data= vet2)
c(overall= coef(fit1)[1],
  t0_60  = coef(fit2)[1],
  t60_120= sum(coef(fit2)[c(1,4)]),
  t120   = sum(coef(fit2)[c(1,5)]))
```

---

tcut *Factors for person-year calculations*

---

## Description

Attaches categories for person-year calculations to a variable without losing the underlying continuous representation

## Usage

```
tcut(x, breaks, labels, scale=1)
## S3 method for class 'tcut'
levels(x)
```

## Arguments

| | |
|---|---|
| x | numeric/date variable |
| breaks | breaks between categories, which are right-continuous |
| labels | labels for categories |
| scale | Multiply x and breaks by this. |

## Value

An object of class tcut

## See Also

cut, pyears

## Examples

```
mdy.date <- function(m,d,y)
   as.Date(paste(ifelse(y<100, y+1900, y), m, d, sep='/'))
temp1 <- mdy.date(6,6,36)
temp2 <- mdy.date(6,6,55)# Now compare the results from person-years
#
temp.age <- tcut(temp2-temp1, floor(c(-1, (18:31 * 365.24))),
labels=c('0-18', paste(18:30, 19:31, sep='-')))
temp.yr  <- tcut(temp2, mdy.date(1,1,1954:1965), labels=1954:1964)
temp.time <- 3700   #total days of fu
py1 <- pyears(temp.time ~ temp.age + temp.yr, scale=1) #output in days
py1
```

`tmerge` *Time based merge for survival data*

## Description

A common task in survival analysis is the creation of start,stop data sets which have multiple intervals for each subject, along with the covariate values that apply over that interval. This function aids in the creation of such data sets.

## Usage

```
tmerge(data1, data2,  id,..., tstart, tstop, options)
```

## Arguments

| | |
|---|---|
| `data1` | the primary data set, to which new variables and/or observation will be added |
| `data2` | second data set in which the other arguments will be found |
| `id` | subject identifier |
| `...` | operations that add new variables or intervals, see below |
| `tstart` | optional variable to define the valid time range for each subject, only used on an initial call |
| `tstop` | optional variable to define the valid time range for each subject, only used on an initial call |
| `options` | a list of options. Valid ones are idname, tstartname, tstopname, delay, na.rm, and tdcstart. See the explanation below. |

## Details

The program is often run in multiple passes, the first of which defines the basic structure, and subsequent ones that add new variables to that structure. For a more complete explanation of how this routine works refer to the vignette on time-dependent variables.

There are 4 types of optional arguments: a time dependent covariate (tdc), cumulative count (cumtdc), event (event) or cumulative event (cumevent). Time dependent covariates change their values before an event, events are outcomes.

- newname = tdc(y, x) A new time dependent covariate variable will created. The argument `y` is assumed to be on the scale of the start and end time, and each instance describes the occurrent of a "condition" at that time. The second argument `x` is optional. In the case where `x` is missing the count variable starts at 0 for each subject and becomes 1 at the time of the event. If `x` is present the value of the time dependent covariate is initialized to the `tdcstart` option and is reset to the value of `x` at each observation. If the option `na.rm=TRUE` missing values of `x` are first removed.

  newname = cumtdc(y,x) Similar to tdc, except that the event count is accumulated over time for each subject.

  newname = event(y,x) Mark an event at time y. In the usual case that `x` is missing the new 0/1 variable will be similar to the 0/1 status variable of a survival time.

  newname = cumevent(y,x) Cumulative events.

The function adds three new variables to the output data set: `tstart`, `tstop`, and `id`. The `options` argument can be used to change these names. The `na.rm` option affects creation of time-dependent covariates. Should a data row in `data2` that has a missing value for the variable be ignored (na.rm=FALSE, default) or should it generate an observation with a value of NA? The default value leads to "last value carried forward" behavior. The `delay` option causes a time-dependent covariate's new value to be delayed, see the vignette for an example.

## Value

a data frame with two extra attributes `tname` and `tcount`. The first contains the names of the key variables; it's persistence from call to call allows the user to avoid constantly reentering the `options` argument. The tcount variable contains counts of the match types. New time values that occur before the first interval for a subject are "early", those after the last interval for a subject are "late", and those that fall into a gap are of type "gap". All these are are considered to be outside the specified time frame for the given subject. An event of this type will be discarded. A time-dependent covariate value will be applied to later intervals but will not generate a new time point in the output.

The most common type will usually be "within", for those new times that fall inside an existing interval and cause it to be split into two. Observations that fall exactly on the edge of an interval but within the (min, max] time for a subject are counted as being on a "leading" edge, "trailing" edge or "boundary". The first corresponds for instance to an occurrence at 17 for someone with an intervals of (0,15] and (17, 35]. A `tdc` at time 17 will affect this interval but an `event` at 17 would be ignored. An `event` occurrence at 15 would count in the (0,15] interval. The last case is where the main data set has touching intervals for a subject, e.g. (17, 28] and (28,35] and a new occurrence lands at the join. Events will go to the earlier interval and counts to the latter one. A last column shows the number of additions where where the id and time point were identical.

These extra attributes are ephemeral and will be discarded if the dataframe is modified in any way. This is intentional.

## Examples

```
# The pbc data set contains baseline data and follow-up status
# for a set of subjects with primary biliary cirrhosis, while the
# pbcseq data set contains repeated laboratory values for those
# subjects.
# The first data set contains data on 312 subjects in a clinical trial plus
# 106 that agreed to be followed off protocol, the second data set has data
# only on the trial subjects.
temp <- subset(pbc, id <= 312, select=c(id:sex, stage)) # baseline data
pbc2 <- tmerge(temp, temp, id=id, endpt = event(time, status))
pbc2 <- tmerge(pbc2, pbcseq, id=id, ascites = tdc(day, ascites),
               bili = tdc(day, bili), albumin = tdc(day, albumin),
               protime = tdc(day, protime), alk.phos = tdc(day, alk.phos))

fit <- coxph(Surv(tstart, tstop, endpt==2) ~ protime + log(bili), data=pbc2)
```

## tobin — *Tobin's Tobit data*

### Description

Economists fit a parametric censored data model called the 'tobit'. These data are from Tobin's original paper.

### Usage

```
tobin
```

### Format

A data frame with 20 observations on the following 3 variables.

**durable** Durable goods purchase

**age** Age in years

**quant** Liquidity ratio (x 1000)

### Source

J Tobin (1958), Estimation of relationships for limited dependent variables. *Econometrica* **26**, 24–36.

### Examples

```
tfit <- survreg(Surv(durable, durable>0, type='left') ~age + quant,
                data=tobin, dist='gaussian')

predict(tfit,type="response")
```

## transplant — *Liver transplant waiting list*

### Description

Subjects on a liver transplant waiting list from 1990-1999, and their disposition: received a transplant, died while waiting, withdrew from the list, or censored.

### Usage

```
data("transplant")
```

## Format

A data frame with 815 observations on the following 6 variables.

`age` age at addition to the waiting list

`sex` `m` or `f`

`abo` blood type: `A`, `B`, `AB` or `O`

`year` year in which they entered the waiting list

`futime` time from entry to final disposition

`event` final disposition: `censored`, `death`, `ltx` or `withdraw`

## Details

This represents the transplant experience in a particular region, over a time period in which liver transplant became much more widely recognized as a viable treatment modality. The number of liver transplants rises over the period, but the number of subjects added to the liver transplant waiting list grew much faster. Important questions addressed by the data are the change in waiting time, who waits, and whether there was an consequent increase in deaths while on the list.

Blood type is an important consideration. Donor livers from subjects with blood type O can be used by patients with A, B, AB or 0 blood types, whereas an Ab liver can only be used by an AB recipient. Thus type O subjects on the waiting list are at a disadvantage, since the pool of competitors is larger for type O donor livers.

This data is of historical interest and provides a useful example of competing risks, but it has little relevance to current practice. Liver allocation policies have evolved and now depend directly on each individual patient's risk and need, assessments of which are regularly updated while a patient is on the waiting list. The overall organ shortage remains acute, however.

## References

Kim WR, Therneau TM, Benson JT, Kremers WK, Rosen CB, Gores GJ, Dickson ER. Deaths on the liver transplant waiting list: An analysis of competing risks. Hepatology 2006 Feb; 43(2):345-51.

## Examples

```
#since event is a factor, survfit creates competing risk curves
pfit <- survfit(Surv(futime, event) ~ abo, transplant)
pfit[,2]  #time to liver transplant, by period
plot(pfit[,2], mark.time=FALSE, col=1:4, lwd=2, xmax=735,
       xscale=30.5, xlab="Months", ylab="Fraction transplanted",
       xaxt = 'n')
temp <- c(0, 6, 12, 18, 24)
axis(1, temp, temp)
legend(450, .35, levels(transplant$abo), lty=1, col=1:4, lwd=2, bty='n')

# competing risks for type O
plot(pfit[4,], xscale=30.5, xmax=735, col=1:3, lwd=2)
legend(450, .4, c("Death", "Transpant", "Withdrawal"), col=1:3, lwd=2)
```

## untangle.specials — *Help Process the 'specials' Argument of the 'terms' Function.*

### Description

Given a `terms` structure and a desired special name, this returns an index appropriate for subscripting the `terms` structure and another appropriate for the data frame.

### Usage

```
untangle.specials(tt, special, order=1)
```

### Arguments

| | |
|---|---|
| `tt` | a `terms` object. |
| `special` | the name of a special function, presumably used in the terms object. |
| `order` | the order of the desired terms. If set to 2, interactions with the special function will be included. |

### Value

a list with two components:

| | |
|---|---|
| `vars` | a vector of variable names, as would be found in the data frame, of the specials. |
| `terms` | a numeric vector, suitable for subscripting the terms structure, that indexes the terms in the expanded model formula which involve the special. |

### Examples

```
formula<-Surv(tt,ss)~x+z*strata(id)
tms<-terms(formula,specials="strata")
## the specials attribute
attr(tms,"specials")
## main effects
untangle.specials(tms,"strata")
## and interactions
untangle.specials(tms,"strata",order=1:2)
```

## uspop2 — *Projected US Population*

### Description

US population by age and sex, for 2000 through 2020

### Usage

```
data(uspop2)
```

### Format

The data is a matrix with dimensions age, sex, and calendar year. Age goes from 0 through 100, where the value for age 100 is the total for all ages of 100 or greater.

### Details

This data is often used as a "standardized" population for epidemiology studies.

### Source

NP2008_D1: Projected Population by Single Year of Age, Sex, Race, and Hispanic Origin for the United States: July 1, 2000 to July 1, 2050, www.census.gov/population/projections.

### See Also

uspop

### Examples

```
us50 <- uspop2[51:101,, "2000"]  #US 2000 population, 50 and over
age <- as.integer(dimnames(us50)[[1]])
smat <- model.matrix( ~ factor(floor(age/5)) -1)
ustot <- t(smat) %*% us50  #totals by 5 year age groups
temp <- c(50,55, 60, 65, 70, 75, 80, 85, 90, 95)
dimnames(ustot) <- list(c(paste(temp, temp+4, sep="-"), "100+"),
                        c("male", "female"))
```

---

## veteran — *Veterans' Administration Lung Cancer study*

---

### Description

Randomised trial of two treatment regimens for lung cancer. This is a standard survival analysis data set.

### Usage

```
veteran
```

### Format

| | |
|---|---|
| trt: | 1=standard 2=test |
| celltype: | 1=squamous, 2=smallcell, 3=adeno, 4=large |
| time: | survival time |
| status: | censoring status |
| karno: | Karnofsky performance score (100=good) |
| diagtime: | months from diagnosis to randomisation |
| age: | in years |
| prior: | prior therapy 0=no, 10=yes |
